3.3 VOLT CMOS SuperSync FIFO™

**FEATURES:**
- Choose among the following memory organizations:
  - IDT72V261LA — 16,384 x 9
  - IDT72V271LA — 32,768 x 9
- Pin-compatible with the IDT72V281/72V291 and IDT72V210/72V211 SuperSync FIFOs
- Functionally compatible with the 5 Volt IDT72261/72271 family
- 10ns read/write cycle time (6.5ns access time)
- Fixed, low first word data latency time
- 5V input tolerant
- Auto power down minimizes standby power consumption
- Partial Reset clears data, but retains programmable settings
- Retransmit operation with fixed, low first word data latency time
- Empty, Full and Half-Full flags signal FIFO status
- Programmable Almost-Empty and Almost-Full flags, each flag can default to one of two preselected offsets
- Program partial flags by either serial or parallel means
- Select IDT Standard timing (using EF and FF flags) or First Word Fall Through timing (using OR and IR flags)
- Output enable puts data outputs into high impedance state
- Easily expandable in depth and width
- Independent Read and Write clocks (permit reading and writing simultaneously)
- Available in the 64-pin Thin Quad Flat Pack (TQFP) and the 64-pin Slim Thin Quad Flat Pack (STQFP)
- High-performance submicron CMOS technology
- Industrial temperature range (–40°C to +85°C) is available
- Green parts available, see ordering information

**DESCRIPTION:**
The IDT72V261LA/72V271LA are functionally compatible versions of the IDT72261/72271 designed to run off a 3.3V supply for very low power consumption. The IDT72V261LA/72V271LA are exceptionally deep, high speed, CMOS First-In-First-Out (FIFO) memories with clocked read and

**FUNCTIONAL BLOCK DIAGRAM**

DESCRIPTION (CONTINUED)

write controls. These FIFOs offer numerous improvements over previous SuperSync FIFOs, including the following:

- The limitation of the frequency of one clock input with respect to the other has been removed. The Frequency Select pin (FS) has been removed, thus it is no longer necessary to select which of the two clock inputs, RCLK or WCLK, is running at the higher frequency.
- The period required by the retransmit operation is now fixed and short.
- The first word data latency period, from the time the first word is written to an empty FIFO to the time it can be read, is now fixed and short. (The variable clock cycle counting delay associated with the latency period found on previous SuperSync devices has been eliminated on this SuperSync family.)

SuperSync FIFOs are particularly appropriate for network, video, telecommunications, data communications and other applications that need to buffer large amounts of data.

The input port is controlled by a Write Clock (WCLK) input and a Write Enable (WEN) input. Data is written into the FIFO on every rising edge of WCLK when WEN is asserted. The output port is controlled by a Read Clock (RCLK) input and Read Enable (REN) input. Data is read from the FIFO on every rising edge of RCLK when REN is asserted. An Output Enable (OE) input is provided for three-state control of the outputs.

The frequencies of both the RCLK and the WCLK signals may vary from 0 to fMAX with complete independence. There are no restrictions on the frequency of one clock input with respect to the other.

NOTES:
1. DC = Don’t Care. Must be tied to GND or Vcc, cannot be left open.
2. This pin may either be tied to ground or left open.
3. DNC = Do Not Connect.
For serial programming, \( \text{SEN} \) together with \( \text{LD} \) on each rising edge of \( \text{WCLK} \), are used to load the offset registers via the Serial Input (SI). For parallel programming, \( \text{WEN} \) together with \( \text{LD} \) on each rising edge of \( \text{WCLK} \), are used to load the offset registers via \( \text{Dn} \). \( \text{REN} \) together with \( \text{LD} \) on each rising edge of \( \text{RCLK} \) can be used to read the offsets in parallel from \( \text{Qn} \) regardless of whether serial or parallel offset loading has been selected.

During Master Reset (MRS) the following events occur: The read and write pointers are set to the first location of the FIFO. The FWFT pin selects IDT Standard mode or FWFT mode. The LD pin selects either a partial flag default setting of 127 with parallel programming or a partial flag default setting of 1,023 with serial programming. The flags are updated according to the timing mode and default offsets selected.

The Partial Reset (PRS) also sets the read and write pointers to the first location of the memory. However, the timing mode, partial flag programming method, and default or programmed offset settings existing before Partial Reset remain unchanged. The flags are updated according to the timing mode and offsets in effect. PRS is useful for resetting a device in mid-operation, when reprogramming partial flags would be undesirable.

The Retransmit function allows data to be reread from the FIFO more than once. A LOW on the \( \text{RT} \) input during a rising \( \text{RCLK} \) edge initiates a retransmit operation by setting the read pointer to the first location of the memory array.

If, at any time, the FIFO is not actively performing an operation, the chip will automatically power down. Once in the power down state, the standby supply current consumption is minimized. Initiating any operation (by activating control inputs) will immediately take the device out of the power down state.

The IDT72V261LA/72V271LA are fabricated using IDT’s high speed submicron CMOS technology.

NOTES:
1. Industrial temperature range product for 15ns speed grade is available as a standard device. All other speed grades are available by special order.
2. Measurements with 0.4 ≤ VIN ≤ VCC.
3. OE ≥ VIH, 0.4 ≤ VOUT ≤ VCC.
4. Tested with outputs disabled (IOUT = 0).
5. RCLK and WCLK toggle at 20 MHz and data inputs switch at 10 MHz.
6. Typical ICC1 = 10 + 0.95*fs + 0.02*Cl*fs (in mA) with VCC = 3.3V, TA = 25°C, fs = WCLK frequency = RCLK frequency (in MHz, using TTL levels), data switching at fs/2, Cl = capacitive load (in pF).
7. All Inputs = Vcc - 0.2V or GND + 0.2V, except RCLK and WCLK, which toggle at 20 MHz.

NOTES:
1. All AC timings apply to both Standard IDT mode and First Word Fall Through mode.
2. Industrial temperature range product for 15ns speed grade is available as a standard device.
3. Pulse widths less than minimum values are not allowed.
4. Values guaranteed by design, not currently tested.

AC TEST CONDITIONS

- Input Pulse Levels: GND to 3.0V
- Input Rise/Fall Times: 3ns
- Input Timing Reference Levels: 1.5V
- Output Reference Levels: 1.5V
- Output Load: See Figure 1

Figure 2. Output Load

* Includes jig and scope capacitances.
FUNCTIONAL DESCRIPTION

TIMING MODES:

IDT STANDARD VS FIRST WORD FALL THROUGH (FWFT) MODE

The IDT72V261LA/72V271LA support two different timing modes of operation: IDT Standard mode or First Word Fall Through (FWFT) mode. The selection of which mode will operate is determined during Master Reset, by the state of the FWFT/SI input.

If, at the time of Master Reset, FWFT/SI is LOW, then IDT Standard mode will be selected. This mode uses the Empty Flag (EF) to indicate whether or not there are any words present in the FIFO. It also uses the Full Flag (FF) to indicate whether or not the FIFO has any free space for writing. In IDT Standard mode, every word read from the FIFO, including the first, must be requested using the Read Enable (REN) and RCLK.

If, at the time of Master Reset, FWFT/SI is HIGH, then FWFT mode will be selected. This mode uses Output Ready (OR) to indicate whether or not there is valid data at the data outputs (Qn). It also uses Input Ready (IR) to indicate whether or not the FIFO has any free space for writing. In the FWFT mode, the first word written to an empty FIFO goes directly to Qn after three RCLK rising edges, REN = LOW is not necessary. Subsequent words must be accessed using the Read Enable (REN) and RCLK.

Various signals, both input and output signals operate differently depending on which timing mode is in effect.

IDT STANDARD MODE

In this mode, the status flags, FF, PAF, HF, PAE, and EF operate in the manner outlined in Table 1. To write data into the FIFO, Write Enable (WEN) must be LOW. Data presented to the DATA IN lines will be clocked into the FIFO on subsequent transitions of the Write Clock (WCLK). After the first write is performed, the Empty Flag (EF) will go HIGH. Subsequent writes will continue to fill up the FIFO. The Programmable Almost-Empty flag (PAE) will go HIGH after n + 1 words have been loaded into the FIFO, where n is the empty offset value. The default setting for this value is stated in the footnote of Table 1. This parameter is also user programmable. See section on Programmable Flag Offset Loading.

If one continued to write data into the FIFO, and we assumed no read operations were taking place, the HF would toggle to LOW once the 8,193rd word for the IDT72V261LA and 16,385th word for the IDT72V271LA, respectively was written into the FIFO. Continuing to write data into the FIFO will cause the PAF to go LOW. Again, if no reads are performed, the PAF will go LOW after (16,385-m) writes for the IDT72V261LA and (32,769-m) writes for the IDT72V271LA, where m is the full offset value. The default setting for this value is stated in the footnote of Table 2. This parameter is also user programmable. See section on Programmable Flag Offset Loading.

If the FIFO is full, the first read operation will cause FF to go HIGH. Subsequent read operations will cause PAF and HF to go HIGH at the conditions described in Table 1. If further read operations occur, without write operations, PAE will go LOW when there are n words in the FIFO, where n is the empty offset value. Continuing read operations will cause the FIFO to become empty. When the last word has been read from the FIFO, the EF will go LOW inhibiting further read operations. REN is ignored when the FIFO is empty.

When configured in IDT Standard mode, the EF and FF outputs are double register-buffered outputs.

Relevant timing diagrams for IDT Standard mode can be found in Figure 7, 8 and 11.

FIRST WORD FALL THROUGH MODE (FWFT)

In this mode, the status flags, IR, PAF, HF, PAE, and OR operate in the manner outlined in Table 2. To write data into the FIFO, WEN must be LOW. Data presented to the DATA IN lines will be clocked into the FIFO on subsequent transitions of WCLK. After the first write is performed, the Output Ready (OR) flag will go LOW. Subsequent writes will continue to fill up the FIFO. PAE will go HIGH after n + 2 words have been loaded into the FIFO, where n is the empty offset value. The default setting for this value is stated in the footnote of Table 2. This parameter is also user programmable. See section on Programmable Flag Offset Loading.

If one continued to write data into the FIFO, and we assumed no read operations were taking place, the HF would toggle to LOW once the 8,194th word for the IDT72V261LA and 16,386th word for the IDT72V271LA, respectively was written into the FIFO. Continuing to write data into the FIFO will cause the PAF to go LOW. Again, if no reads are performed, the PAF will go LOW after (16,385-m) writes for the IDT72V261LA and (32,769-m) writes for the IDT72V271LA, where m is the full offset value. The default setting for this value is stated in the footnote of Table 2.

When the FIFO is full, the Input Ready (IR) flag will go HIGH, inhibiting further write operations. If no reads are performed after a reset, IR will go HIGH after D words to the FIFO. D = 16,385 writes for the IDT72V261LA and 32,769 writes for the IDT72V271LA, respectively. Note that the additional word in FWFT mode is due to the capacity of the memory plus output register.

If the FIFO is full, the first read operation will cause the IR flag to go LOW. Subsequent read operations will cause the PAF and HF to go HIGH at the conditions described in Table 2. If further read operations occur, without write operations, the PAE will go LOW when there are n + 1 words in the FIFO, where n is the empty offset value. Continuing read operations will cause the FIFO to become empty. When the last word has been read from the FIFO, OR will go HIGH inhibiting further read operations. REN is ignored when the FIFO is empty.

When configured in FWFT mode, the OR flag output is triple register-buffered, and the IR flag output is double register-buffered.

Relevant timing diagrams for FWFT mode can be found in Figure 9, 10 and 12.
PROGRAMMING FLAG OFFSETS

Full and Empty Flag offset values are user programmable. The IDT72V261LA/72V271LA has internal registers for these offsets. Default settings are stated in the footnotes of Table 1 and Table 2. Offset values can be programmed into the FIFO in one of two ways; serial or parallel loading method. The selection of the loading method is done using the LD (Load) pin. During Master Reset, the state of the LD input determines whether serial or parallel flag offset programming is enabled. A HIGH on LD during Master Reset selects serial loading of offset values and in addition, sets a default PAE offset value of 3FFH (a threshold 1,023 words from the empty boundary), and a default PAF offset value of 3FFH (a threshold 1,023 words from the full boundary). A LOW on LD during Master Reset selects parallel loading of offset values, and in addition, sets a default PAE offset value of 07FH (a threshold 127 words from the empty boundary), and a default PAF offset value of 07FH (a threshold 127 words from the full boundary). See Figure 3, Offset Register Location and Default Values.

In addition to loading offset values into the FIFO, it is also possible to read the current offset values. It is only possible to read offset values via parallel read.

Figure 4, Programmable Flag Offset Programming Sequence, summarizes the control pins and sequence for both serial and parallel programming modes. For a more detailed description, see discussion that follows.

The offset registers may be programmed (and reprogrammed) any time after Master Reset, regardless of whether serial or parallel programming has been selected.

**NOTES:**
1. The programming method can only be selected at Master Reset.
2. Parallel reading of the offset registers is always permitted regardless of which programming method has been selected.
3. The programming sequence applies to both IDT Standard and FWFT modes.

*Figure 4. Programmable Flag Offset Programming Sequence*
SERIAL PROGRAMMING MODE

If Serial Programming mode has been selected, as described above, then programming of $\text{PAE}$ and $\text{PAF}$ values can be achieved by using a combination of the $\text{LD}$, $\text{SEN}$, $\text{WCLK}$ and $\text{SI}$ input pins. Programming $\text{PAE}$ and $\text{PAF}$ proceeds as follows: when $\text{LD}$ and $\text{SEN}$ are set LOW, data on the $\text{SI}$ input are written, one bit for each $\text{WCLK}$ rising edge, starting with the Empty Offset LSB and ending with the Full Offset MSB. A total of 28 bits for the IDT72V261LA and 30 bits for the IDT72V271LA. See Figure 13, Serial Loading of Programmable Flag Registers, for the timing diagram for this mode.

Using the serial method, individual registers cannot be programmed selectively. $\text{PAE}$ and $\text{PAF}$ can show a valid status only after the complete set of bits (for all offset registers) has been entered. The registers can be reprogrammed as long as the complete set of new offset bits is entered. When $\text{LD}$ is LOW and $\text{SEN}$ is HIGH, no serial write to the registers can occur.

Write operations to the FIFO are allowed before and during the serial programming sequence. In this case, the programming of all offset bits does not have to occur at once. A select number of bits can be written to the $\text{SI}$ input and then, by bringing $\text{WCLK}$ HIGH, data can be written to FIFO memory via $\text{Dn}$ by toggling $\text{WEN}$. When $\text{WEN}$ is brought HIGH with $\text{LD}$ and $\text{SEN}$ restored to a LOW, the next offset bit in sequence is written to the registers via $\text{SI}$. If an interruption of serial programming is desired, it is sufficient either to set $\text{LD}$ LOW and deactivate $\text{SEN}$ or to set $\text{SEN}$ LOW and deactivate $\text{LD}$. Once $\text{LD}$ and $\text{SEN}$ are both restored to a LOW level, serial offset programming continues.

From the time serial programming has begun, neither partial flag will be valid until the full set of bits required to fill all the offset registers has been written. Measuring from the rising $\text{WCLK}$ edge that achieves the above criteria; $\text{PAF}$ will be valid after two more rising $\text{WCLK}$ edges plus $t_{\text{PAF}}, \text{PAE}$ will be valid after the next two rising $\text{RCLK}$ edges plus $t_{\text{PAE}} + t_{\text{skew}}$.

It is not possible to read the flag offset values in a serial mode.

PARALLEL MODE

If Parallel Programming mode has been selected, as described above, then programming of $\text{PAE}$ and $\text{PAF}$ values can be achieved by using a combination of the $\text{LD}$, $\text{WCLK}$, $\text{WEN}$ and $\text{Dn}$ input pins. For the IDT72V261LA and the IDT72V271LA, programming $\text{PAE}$ and $\text{PAF}$ proceeds as follows: when $\text{LD}$ and $\text{WEN}$ are set LOW, data on the inputs $\text{Dn}$ are written into the Empty Offset LSB Register on the first LOW-to-HIGH transition of $\text{WCLK}$. Upon the second LOW-to-HIGH transition of $\text{WCLK}$, data are written into the Empty Offset MSB Register. Upon the third LOW-to-HIGH transition of $\text{WCLK}$, data are written into the Full Offset LSB Register. Upon the fourth LOW-to-HIGH transition of $\text{WCLK}$, data are written into the Full Offset MSB Register. The fifth transition of $\text{WCLK}$ writes, once again, to the Empty Offset LSB Register. See Figure 14, Parallel Loading of Programmable Flag Registers for the IDT72V261LA, for the timing diagram for this mode.

The act of writing offsets in parallel employs a dedicated write offset register pointer. The act of reading offsets employs a dedicated read offset register pointer. The two pointers operate independently; however, a read and a write should not be performed simultaneously to the offset registers. A Master Reset initializes both pointers to the Empty Offset (LSB) register. A Partial Reset has no effect on the position of these pointers.

Write operations to the FIFO are allowed before and during the parallel programming sequence. In this case, the programming of all offset registers does not have to occur at one time. One, two or more offset registers can be written and then by bringing $\text{LD}$ HIGH, write operations can be redirected to the FIFO memory. When $\text{LD}$ is set LOW again, and $\text{WEN}$ is LOW, the next offset register in sequence is written to. As an alternative to holding $\text{WEN}$ LOW and toggling $\text{LD}$, parallel programming can also be interrupted by setting $\text{LD}$ LOW and toggling $\text{WEN}$.

Note that the status of a partial flag ($\text{PAE}$ or $\text{PAF}$) output is invalid during the programming process. From the time parallel programming has begun, a partial flag output will not be valid until the appropriate offset word has been written to the register(s) pertaining to that flag. Measuring from the rising $\text{WCLK}$ edge that achieves the above criteria; $\text{PAF}$ will be valid after two more rising $\text{WCLK}$ edges plus $t_{\text{PAF}}, \text{PAE}$ will be valid after the next two rising $\text{RCLK}$ edges plus $t_{\text{PAE}} + t_{\text{skew}}$.

The act of reading the offset registers employs a dedicated read offset register pointer. The contents of the offset registers can be read on the $Q_0$-$Q_n$ pins when $\text{LD}$ is set LOW and $\text{REN}$ is set LOW. For the IDT72V261LA and IDT72V271LA, data are read via $\text{Qn}$ from the Empty Offset LSB Register on the first LOW-to-HIGH transition of $\text{RCLK}$. Upon the second LOW-to-HIGH transition of $\text{RCLK}$, data are read from the Empty Offset MSB Register. Upon the third LOW-to-HIGH transition of $\text{RCLK}$, data are read from the Full Offset LSB Register. Upon the fourth LOW-to-HIGH transition of $\text{RCLK}$, data are read from the Full Offset MSB Register. The fifth transition of $\text{RCLK}$ reads, once again, from the Empty Offset LSB Register. See Figure 15, Parallel Read of Programmable Flag Registers for the IDT72V261LA, for the timing diagram for this mode.

It is permissible to interrupt the offset register read sequence with reads or writes to the FIFO. The interruption is accomplished by deasserting $\text{REN}$, $\text{LD}$, or both together. When $\text{REN}$ and $\text{LD}$ are restored to a LOW level, reading of the offset registers continues where it left off. It should be noted, and care should be taken from the fact that when a parallel read of the flag offsets is performed, the data word that was present on the output lines $\text{Qn}$ will be overwritten.

Parallel reading of the offset registers is always permitted regardless of which timing mode (IDT Standard or FWFT modes) has been selected.

RETRANSMIT OPERATION

The Retransmit operation allows data that has already been read to be accessed again. There are two stages: first, a setup procedure that resets the read pointer to the first location of memory, then the actual retransmit, which consists of reading out the memory contents, starting at the beginning of memory.

Retransmit setup is initiated by holding $\text{RT}$ LOW during a rising $\text{RCLK}$ edge. $\text{REN}$ and $\text{WEN}$ must be HIGH before bringing $\text{RT}$ LOW. At least one word, but no more than $D - 2$ words should have been written into the FIFO between Reset (Master or Partial) and the time of Retransmit setup. $D = 16,384$ for the IDT72V261LA and $D = 32,768$ for the IDT72V271LA in IDT Standard mode. In FWFT mode, $D = 16,385$ for the IDT72V261LA and $D = 32,769$ for the IDT72V271LA.

If IDT Standard mode is selected, the FIFO will mark the beginning of the Retransmit setup by setting $\text{EF}$ LOW. The change in level will only be noticeable if $\text{EF}$ was HIGH before setup. During this period, the internal read pointer is initialized to the first location of the RAM array.
When EF goes HIGH, Retransmit setup is complete and read operations may begin starting with the first location in memory. Since IDT Standard mode is selected, every word read including the first word following Retransmit setup requires a LOW on REN to enable the rising edge of RCLK. See Figure 11, Retransmit Timing (IDT Standard Mode), for the relevant timing diagram.

If FWFT mode is selected, the FIFO will mark the beginning of the Retransmit setup by setting OR HIGH. During this period, the internal read pointer is set to the first location of the RAM array.

When OR goes LOW, Retransmit setup is complete; at the same time, the contents of the first location appear on the outputs. Since FWFT mode is selected, the first word appears on the outputs, no LOW on REN is necessary. Reading all subsequent words requires a LOW on REN to enable the rising edge of RCLK. See Figure 12, Retransmit Timing (FWFT Mode), for the relevant timing diagram.

For either IDT Standard mode or FWFT mode, updating of the PAE, HF and PAF flags begin with the rising edge of RCLK that RT is setup. PAE is synchronized to RCLK, thus on the second rising edge of RCLK after RT is setup, the PAE flag will be updated. HF is asynchronous, thus the rising edge of RCLK that RT is setup will update HF. PAF is synchronized to WCLK, thus the second rising edge of WCLK that occurs tSKEW after the rising edge of RCLK that RT is setup will update PAF. RT is synchronized to RCLK.
SIGNAL DESCRIPTION

INPUTS:
DATA IN (D0 - Do)
Data inputs for 9-bit wide data.

CONTROLS:
MASTER RESET (MRS)
A Master Reset is accomplished whenever the MRS input is taken to a LOW state. This operation sets the internal read and write pointers to the first location of the RAM array. PAE will go LOW, PAF will go HIGH, and HF will go HIGH.

If FWFT is LOW during Master Reset then the IDT Standard mode, along with EF and FF are selected. EF will go LOW and FF will go HIGH. If FWFT is HIGH, then the First Word Fall Through mode (FWFT), along with IR and OR, are selected. OR will go HIGH and IR will go LOW.

If LD is LOW during Master Reset, then PAE is assigned a threshold 127 words from the empty boundary and PAF is assigned a threshold 127 words from the full boundary; 127 words corresponds to an offset value of 07FH. Following Master Reset, parallel loading of the offsets is permitted, but not serial loading.

If LD is HIGH during Master Reset, then PAE is assigned a threshold 1,023 words from the empty boundary and PAF is assigned a threshold 1,023 words from the full boundary; 1,023 words corresponds to an offset value of 3FFH. Following Master Reset, serial loading of the offsets is permitted, but not parallel loading.

Parallel reading of the registers is always permitted. (See section describing the LD pin for further details.) During a Master Reset, the output register is initialized to all zeroes. A Master Reset is required after power up, before a write operation can take place. MRS is asynchronous.

See Figure 5, Master Reset Timing, for the relevant timing diagram.

PARTIAL RESET (PRS)
A Partial Reset is accomplished whenever the PRS input is taken to a LOW state. As in the case of the Master Reset, the internal read and write pointers are set to the first location of the RAM array, PAE goes LOW, PAF goes HIGH, and HF goes HIGH.

Whichever mode is active at the time of Partial Reset, IDT Standard mode or First Word Fall Through, that mode will remain selected. If the IDT Standard mode is active, then FF will go HIGH and EF will go LOW. If the First Word Fall Through mode is active, then OR will go HIGH, and IR will go LOW.

Following Partial Reset, all values held in the offset registers remain unchanged. The programming method (parallel or serial) currently active at the time of Partial Reset is also retained. The output register is initialized to all zeroes. PRS is asynchronous.

A Partial Reset is useful for resetting the device during the course of operation, when reprogramming partial flag offset settings may not be convenient.

See Figure 6, Partial Reset Timing, for the relevant timing diagram.

RETRANSMIT (RT)
The Retransmit operation allows data that has already been read to be accessed again. There are two stages: first, a setup procedure that resets the read pointer to the first location of memory, then the actual retransmit, which consists of reading out the memory contents, starting at the beginning of the memory.

Retransmit setup is initiated by holding RT LOW during a rising RCLK edge. REN and WEN must be HIGH before bringing RT LOW.

If IDT Standard mode is selected, the FIFO will mark the beginning of the Retransmit setup by clearing EF LOW. The change in level will only be noticeable if EF was HIGH before setup. During this period, the internal read pointer is initialized to the first location of the RAM array.

When EF goes HIGH, Retransmit setup is complete and read operations may begin starting with the first location in memory. Since IDT Standard mode is selected, every word read including the first word following Retransmit setup requires a LOW on REN to enable the rising edge of RCLK. See Figure 11, Retransmit Timing (IDT Standard Mode), for the relevant timing diagram.

If FWFT mode is selected, the FIFO will mark the beginning of the Retransmit setup by setting OR HIGH. During this period, the internal read pointer is set to the first location of the RAM array.

When OR goes LOW, Retransmit setup is complete; at the same time, the contents of the first location appear on the outputs. Since FWFT mode is selected, the first word appears on the outputs, no LOW on REN is necessary. Reading all subsequent words requires a LOW on REN to enable the rising edge of RCLK. See Figure 12, Retransmit Timing (FWFT Mode), for the relevant timing diagram.

FIRST WORD FALL THROUGH/Serial IN (FWFT/SI)
This is a dual purpose pin. During Master Reset, the state of the FWFT/SI input determines whether the device will operate in IDT Standard mode or First Word Fall Through (FWFT) mode. If, at the time of Master Reset, FWFT/SI is LOW, then IDT Standard mode will be selected. This mode uses the Empty Flag (EF) to indicate whether or not there are any words present in the FIFO memory. It also uses the Full Flag function (FF) to indicate whether or not the FIFO memory has any free space for writing.

In IDT Standard mode, every word read from the FIFO, including the first, must be requested using the Read Enable (REN) and RCLK.

If, at the time of Master Reset, FWFT/SI is HIGH, then FWFT mode will be selected. This mode uses Output Ready (OR) to indicate whether or not there is valid data at the data outputs (Qn). It also uses Input Ready (IR) to indicate whether or not the FIFO memory has any free space for writing. In the FWFT mode, the first word written to an empty FIFO goes directly to Qn after three RCLK rising edges. REN = LOW is not necessary. Subsequent words must be accessed using the Read Enable (REN) and RCLK.

After Master Reset, FWFT/SI acts as a serial input for loading PAE and PAF offsets into the programmable registers. The serial input function can only be used when the serial loading method has been selected during Master Reset. Serial programming using the FWFT/SI pin functions the same way in both IDT Standard and FWFT modes.
WRITE CLOCK (WCLK)
A write cycle is initiated on the rising edge of the WCLK input. Data setup and hold times must be met with respect to the LOW-to-HIGH transition of the WCLK. It is permissible to stop the WCLK. Note that while WCLK is idle, the FF/IR, PAF and HF flags will not be updated. (Note that WCLK is only capable of updating HF flag to LOW.) The Write and Read Clocks can either be independent or coincident.

WRITE ENABLE (WEN)
When the WEN input is LOW, data may be loaded into the FIFO RAM array on the rising edge of every WCLK cycle if the device is not full. Data is stored in the RAM array sequentially and independently of any ongoing read operation.

When WEN is HIGH, no new data is written in the RAM array on each WCLK cycle.

To prevent data overflow in the IDT Standard mode, FF will go LOW, inhibiting further write operations. Upon the completion of a valid read cycle, FF will go HIGH allowing a write to occur. The FF is updated by two WCLK cycles + tSKEW after the RCLK cycle.

To prevent data overflow in the FWFT mode, IR will go HIGH, inhibiting further write operations. Upon the completion of a valid read cycle, IR will go LOW allowing a write to occur. The IR flag is updated by two WCLK cycles + tSKEW after the valid RCLK cycle.

WEN is ignored when the FIFO is full in either FWFT or IDT Standard mode.

READ CLOCK (RCLK)
A read cycle is initiated on the rising edge of the RCLK input. Data can be read on the outputs, on the rising edge of the RCLK input. It is permissible to stop the RCLK. Note that while RCLK is idle, the EF/OR, PAE and HF flags will not be updated. (Note that RCLK is only capable of updating the HF flag to HIGH.) The Write and Read Clocks can be independent or coincident.

READ ENABLE (REN)
When Read Enable is LOW, data is loaded from the RAM array into the output register on the rising edge of every RCLK cycle if the device is not empty.

When the REN input is HIGH, the output register holds the previous data and no new data is loaded into the output register. The data outputs Q0-Qn maintain the previous data value.

In the IDT Standard mode, every word accessed at Qn, including the first word written to an empty FIFO, must be requested using REN. When the last word has been read from the FIFO, the Empty Flag (EF) will go LOW, inhibiting further read operations. REN is ignored when the FIFO is empty. Once a write is performed, EF will go HIGH allowing a read to occur. The EF flag is updated by two RCLK cycles + tSKEW after the valid WCLK cycle.

In the FWFT mode, the first word written to an empty FIFO automatically goes to the outputs Qn on the third valid LOW to HIGH transition of RCLK + tSKEW after the first write. REN does not need to be asserted LOW. In order to access all other words, a read must be executed using REN. The RCLK LOW to HIGH transition after the last word has been read from the FIFO, Output Ready (OR) will go HIGH with a true read (RCLK with REN = LOW), inhibiting further read operations. REN is ignored when the FIFO is empty.

SERIAL ENABLE (SEN)
The SEN input is an enable used only for serial programming of the offset registers. The serial programming method must be selected during Master Reset. SEN is always used in conjunction with LD. When these lines are both LOW, data at the SI input can be loaded into the program register one bit at a time with LOW-to-HIGH transition of WCLK. (See Figure 4.)

When SEN is HIGH, the programmable registers retain the previous settings and no offsets are loaded. SEN functions the same way in both IDT Standard and FWFT modes.

OUTPUT ENABLE (OE)
When Output Enable is enabled (LOW), the parallel output buffers receive data from the output register. When OE is HIGH, the output data bus (Qn) goes into a high impedance state.

LOAD (LD)
This is a dual purpose pin. During Master Reset, the state of the LD input determines one of two default offset values (127 or 1,023) for the PAE and PAF flags, along with the method by which these offset registers can be programmed, parallel or serial. After Master Reset, LD enables write operations to and read operations from the offset registers. Only the offset loading method currently selected can be used to write to the registers. Offset registers can be read only in parallel. A LOW on LD during Master Reset selects a default PAF offset value of 07FH (a threshold 127 words from the empty boundary), a default PAF offset value of 07FH (a threshold 127 words from the full boundary), and parallel loading of other offset values. A HIGH on LD during Master Reset selects a default PAF offset value of 3FFH (a threshold 1,023 words from the empty boundary), a default PAF offset value of 3FFH (a threshold 1,023 words from the full boundary), and serial loading of other offset values.

After Master Reset, the LD pin is used to activate the programming process of the flag offset values PAE and PAF. Pulling LD LOW will begin a serial loading or parallel load or read of these offset values. See Figure 4, Programmable Flag Offset Programming Sequence.

OUTPUTS:
FULL FLAG (FF/IR)
This is a dual purpose pin. In IDT Standard mode, the Full Flag (FF) function is selected. When the FIFO is full, FF will go LOW, inhibiting further write operations. When FF is HIGH, the FIFO is not full. If no reads are performed after a reset (either MRS or PRS), FF will go LOW after D writes to the FIFO (D = 16,384 for the IDT72V261LA and 32,768 for the IDT72V271LA). See Figure 7, Write Cycle and Full Flag Timing (IDT Standard Mode), for the relevant timing information.

In FWFT mode, the Input Ready (IR) function is selected. IR goes LOW when memory space is available for writing in data. When there is no longer any free space left, IR goes HIGH, inhibiting further write operations. If no reads are performed after a reset (either MRS or PRS), IR will go HIGH after D writes to the FIFO (D = 16,385 for the IDT72V261LA and 32,769 for the IDT72V271LA). See Figure 9, Write Timing (FWFT Mode), for the relevant timing information.

The IR status not only measures the contents of the FIFO memory, but also counts the presence of a word in the output register. Thus, in
FWFT mode, the total number of writes necessary to deassert IR is one greater than needed to assert FF in IDT Standard mode.

FF/IR is synchronized and updated on the rising edge of WCLK. FF/IR are double register-buffered outputs.

**EMPTY FLAG (EF/ OR)**

This is a dual purpose pin. In the IDT Standard mode, the Empty Flag (EF) function is selected. When the FIFO is empty, EF will go LOW, inhibiting further read operations. When EF is HIGH, the FIFO is not empty. See Figure 8, Read Cycle, Empty Flag and First Word Latency Timing (IDT Standard Mode), for the relevant timing information.

In FWFT mode, the Output Ready (OR) function is selected. OR goes LOW at the same time that the first word written to an empty FIFO appears valid on the outputs. OR stays LOW after the RCLK LOW to HIGH transition that shifts the last word from the FIFO memory to the outputs. OR goes HIGH only with a true read (RCLK with REN = LOW). The previous data stays at the outputs, indicating the last word was read. Further data reads are inhibited until OR goes LOW again. See Figure 10, Read Timing (FWFT Mode), for the relevant timing information.

EF/ OR is synchronous and updated on the rising edge of RCLK.

In IDT Standard mode, EF is a double register-buffered output. In FWFT mode, OR is a triple register-buffered output.

**PROGRAMMABLE ALMOST-FULL FLAG (PAF)**

The Programmable Almost-Full flag (PAF) will go LOW when the FIFO reaches the almost-full condition. In IDT Standard mode, PAF will go LOW when there are \( n \) words or less in the FIFO. The offset “\( n \)” is the empty offset value. The default setting for this value is stated in the footnote of Table 1.

In FWFT mode, the \( \text{PAF} \) will go LOW when there are \( n+1 \) words or less in the FIFO. The default setting for this value is stated in the footnote of Table 2.

See Figure 16, Programmable Almost-Full Flag Timing (IDT Standard and FWFT Mode), for the relevant timing information. PAF is synchronous and updated on the rising edge of WCLK.

**PROGRAMMABLE ALMOST-EMPTY FLAG (PAE)**

The Programmable Almost-Empty flag (PAE) will go LOW when the FIFO reaches the almost-empty condition. In IDT Standard mode, PAE will go LOW when there are \( n \) words or less in the FIFO. The offset “\( n \)” is the empty offset value. The default setting for this value is stated in the footnote of Table 1.

In FWFT mode, the \( \text{PAE} \) will go LOW when there are \( n+1 \) words or less in the FIFO. The default setting for this value is stated in the footnote of Table 2.

See Figure 17, Programmable Almost-Empty Flag Timing (IDT Standard and FWFT Mode), for the relevant timing information. PAE is synchronous and updated on the rising edge of RCLK.

**HALF-FULL FLAG (HF)**

This output indicates a half-full FIFO. The rising WCLK edge that fills the FIFO beyond half-full sets HF LOW. The flag remains LOW until the difference between the write and read pointers becomes less than or equal to half of the total depth of the device; the rising RCLK edge that accomplishes this condition sets HF HIGH.

In IDT Standard mode, if no reads are performed after reset (MRS or PRS), HF will go LOW after \( (D/2 + 1) \) writes to the FIFO, where \( D = 16,384 \) for the IDT72V261LA and 32,768 for the IDT72V271LA.

In FWFT mode, if no reads are performed after reset (MRS or PRS), HF will go LOW after \( (D-1/2 + 2) \) writes to the FIFO, where \( D = 16,385 \) for the IDT72V261LA and 32,769 for the IDT72V271LA.

See Figure 18, Half-Full Flag Timing (IDT Standard and FWFT Modes), for the relevant timing information. Because HF is updated by both RCLK and WCLK, it is considered asynchronous.

**DATA OUTPUTS (Q0-Q8)**

(Q0 - Q8) are data outputs for 9-bit wide data.
Figure 5. Master Reset Timing

$t_{RSR}$

$t_{RSF}$

$OE$ = HIGH

$OE$ = LOW
Figure 6. Partial Reset Timing
NOTES:
1. \( t_{SKEW1} \) is the minimum time between a rising RCLK edge and a rising WCLK edge to guarantee that \( FF \) will go high (after one WCLK cycle plus \( twFF \)). If the time between the rising edge of the RCLK and the rising edge of the WCLK is less than \( t_{SKEW1} \), then the \( FF \) deassertion may be delayed one extra WCLK cycle.
2. \( LD = \text{HIGH}, \ OE = \text{LOW}, \ EF = \text{HIGH} \)

**Figure 7. Write Cycle and Full Flag Timing (IDT Standard Mode)**

NOTES:
1. \( t_{SKEW3} \) is the minimum time between a rising WCLK edge and a rising RCLK edge to guarantee that \( EF \) will go high (after one WCLK cycle plus \( twFF \)). If the time between the rising edge of the WCLK and the rising edge of the RCLK is less than \( t_{SKEW3} \), then the \( EF \) deassertion may be delayed one extra WCLK cycle.
2. \( LD = \text{HIGH} \)
3. First word latency: \( 60\text{ns} + t_{REF} + 1\times t_{RCLK} \)

**Figure 8. Read Cycle, Empty Flag and First Data Word Latency Timing (IDT Standard Mode)**
NOTES:

1. $t_{SKEW3}$ is the minimum time between a rising WCLK edge and a rising RCLK edge to guarantee that $OR$ will go LOW after two RCLK cycles plus $t_{REF}$. If the time between the rising edge of WCLK and the rising edge of RCLK is less than $t_{SKEW3}$, then $OR$ assertion may be delayed one extra RCLK cycle.

2. $t_{SKEW2}$ is the minimum time between a rising WCLK edge and a rising RCLK edge to guarantee that $PAE$ will go HIGH after one RCLK cycle plus $t_{PAE}$. If the time between the rising edge of WCLK and the rising edge of RCLK is less than $t_{SKEW2}$, then the $PAE$ deassertion may be delayed one extra RCLK cycle.

3. $LD = \text{HIGH}, \ OE = \text{LOW}$

4. $n = PAE$ offset, $m = PAF$ offset and $D = \text{maximum FIFO depth}$.

5. $D = 16,385$ for the IDT72V261LA and 32,769 for the IDT72V271LA.

6. First word latency: $60\text{ns} + t_{REF} + 2\times t_{RCLK}$.

Figure 9. Write Timing (First Word Fall Through Mode)
NOTES:
1. $t_{SKEW1}$ is the minimum time between a rising RCLK edge and a rising WCLK edge to guarantee that $R$ will go LOW after one WCLK cycle plus $t_{WFF}$. If the time between the rising edge of RCLK and the rising edge of WCLK is less than $t_{SKEW1}$, then the $R$ assertion may be delayed one extra WCLK cycle.
2. $t_{SKEW2}$ is the minimum time between a rising RCLK edge and a rising WCLK edge to guarantee that $PAF$ will go HIGH after one WCLK cycle plus $t_{PAF}$. If the time between the rising edge of RCLK and the rising edge of WCLK is less than $t_{SKEW2}$, then the $PAF$ deassertion may be delayed one extra WCLK cycle.
3. $L_D = HIGH$
4. $n = PAE$ offset, $m = PAF$ offset and $D =$ maximum FIFO depth.
5. $D = 16,385$ for the IDT72V261LA and 32,769 for the IDT72V271LA.

Figure 10. Read Timing (First Word Fall Through Mode)
Figure 11. Retransmit Timing (IDT Standard Mode)

NOTES:
1. Retransmit setup is complete after \( \text{EF} \) returns HIGH, only then can a read operation begin.
2. \( \text{OE} = \text{LOW} \).
3. \( W_1 \) = first word written to the FIFO after Master Reset, \( W_2 \) = second word written to the FIFO after Master Reset.
4. No more than \( D - 2 \) may be written to the FIFO between Reset (Master or Partial) and Retransmit setup. Therefore, \( FF \) will be HIGH throughout the Retransmit setup procedure. \( D = 16,384 \) for IDT72V261LA and 32,768 for IDT72V271LA.
5. \( \text{EF} \) goes HIGH at 60 ns + 1 RCLK cycle + \( t_{\text{REF}} \).
NOTES:
1. Retransmit setup is complete after OR returns LOW.
2. No more than D - 2 words may be written to the FIFO between Reset (Master or Partial) and Retransmit setup. Therefore, IR will be LOW throughout the Retransmit setup procedure. D = 16,385 for the IDT72V261LA and 32,769 for the IDT72V271LA.
3. OE = LOW.
4. W1, W2, W3 = first, second and third words written to the FIFO after Master Reset.
5. OR goes LOW at 60 ns + 2 RCLK cycles + tREF.

Figure 12. Retransmit Timing (FWFT Mode)

NOTE:
1. X = 13 for the IDT72V261LA and X = 14 for the IDT72V271LA.
Figure 14. Parallel Loading of Programmable Flag Registers (IDT Standard and FWFT Modes)

Figure 15. Parallel Read of Programmable Flag Registers (IDT Standard and FWFT Modes)

NOTE:
1. OE = LOW.
### NOTES:
1. For IDT Standard mode: \( D = \) maximum FIFO depth.
2. For FWFT mode: \( D = \) maximum FIFO depth.

#### Figure 16. Programmable Almost-Full Flag Timing (IDT Standard and FWFT Modes)

### NOTES:
1. \( m = \) PAF offset.
2. \( D = \) maximum FIFO depth.
   - In IDT Standard mode: \( D = 16,384 \) for the IDT72V261LA and 32,768 for the IDT72V271LA.
   - In FWFT mode: \( D = 16,385 \) for the IDT72V261LA and 32,769 for the IDT72V271LA.
3. \( t_{SKEW2} \) is the minimum time between a rising RCLK edge and a rising WCLK edge to guarantee that \( PAE \) will go HIGH (after one RCLK cycle plus \( t_{PAE} \)). If the time between the rising edge of RCLK and the rising edge of WCLK is less than \( t_{SKEW2} \), then the \( PAE \) deassertion time may be delayed one extra WCLK cycle.
4. \( PAF \) is asserted and updated on the rising edge of WCLK only.

### Figure 17. Programmable Almost-Empty Flag Timing (IDT Standard and FWFT Modes)

### NOTES:
1. \( n = \) PAE offset.
2. For IDT Standard mode.
3. For FWFT mode.
4. \( t_{SKEW2} \) is the minimum time between a rising WCLK edge and a rising RCLK edge to guarantee that \( PAE \) will go HIGH (after one RCLK cycle plus \( t_{PAE} \)). If the time between the rising edge of WCLK and the rising edge of RCLK is less than \( t_{SKEW2} \), then the \( PAE \) deassertion time may be delayed one extra RCLK cycle.
5. \( PAE \) is asserted and updated on the rising edge of WCLK only.

### Figure 18. Half-Full Timing (IDT Standard and FWFT Modes)
OPTIONAL CONFIGURATIONS

WIDTH EXPANSION CONFIGURATION

Word width may be increased simply by connecting together the control signals of multiple devices. Status flags can be detected from any one device. The exceptions are the \( \text{EF} \) and \( \text{FF} \) functions in IDT Standard mode and the \( \text{IR} \) and \( \text{OR} \) functions in FWFT mode. Because of variations in skew between RCLK and WCLK, it is possible for \( \text{EF}/\text{FF} \) deassertion and \( \text{IR}/\text{OR} \) assertion to vary by one cycle between FIFOs. In IDT Standard mode, such problems can be avoided by creating composite flags, that is, ANDing \( \text{EF} \) of every FIFO, and separately ANDing \( \text{FF} \) of every FIFO. In FWFT mode, composite flags can be created by ORing \( \text{OR} \) of every FIFO, and separately ORing \( \text{IR} \) of every FIFO.

Figure 21 demonstrates a width expansion using two IDT72V261LA/72V271LA devices. D0 - D8 from each device form a 18-bit wide input bus and Q0-Q8 from each device form a 18-bit wide output bus. Any word width can be attained by adding additional IDT72V261LA/72V271LA devices.

Notes:
1. Use an AND gate in IDT Standard mode, an OR gate in FWFT mode.
2. Do not connect any output control signals directly together.
3. FIFO #1 and FIFO #2 must be the same depth, but may be different word widths.

Figure 19. Block Diagram of 16,384 x 18 and 32,768 x 18 Width Expansion
DEPTH EXPANSION CONFIGURATION (FWFT MODE ONLY)

The IDT72V261LA can easily be adapted to applications requiring depths greater than 16,384 and 32,768 for the IDT72V271LA with a 9-bit bus width. In FWFT mode, the FIFOs can be connected in series (the data outputs of one FIFO connected to the data inputs of the next) without any external logic necessary. The resulting configuration provides an overall depth equivalent to the sum of the depths associated with each single FIFO. Figure 22 shows a depth expansion using two IDT72V261LA/72V271LA devices.

Care should be taken to select FWFT mode during Master Reset for all FIFOs in the depth expansion configuration. The first word written to an empty configuration will pass from one FIFO to the next ("ripple down") until it finally appears at the outputs of the last FIFO in the chain—no read operation is necessary but the RCLK of each FIFO must be free-running. Each time the data word appears at the outputs of one FIFO, that device's OR line goes LOW, enabling a write to the next FIFO in line.

For an empty expansion configuration, the amount of time it takes for the OR flag of the last FIFO in the chain to go LOW (i.e., valid data to appear on the last FIFO's outputs) after a word has been written to the first FIFO is the sum of the delays for each individual FIFO:

\[(N - 1) \times (4 \times \text{transfer clock}) + 3 \times \text{TRCLK}\]

where \(N\) is the number of FIFOs in the expansion and TRCLK is the RCLK period. Note that extra cycles should be added for the possibility that the tSKEW3 specification is not met between WCLK and transfer clock, or RCLK and transfer clock, for the OR flag.

The "ripple down" delay is only noticeable for the first word written to an empty depth expansion configuration. There will be no delay evident for subsequent words written to the configuration.

The first free location created by reading from a full depth expansion configuration will "bubble up" from the last FIFO to the previous one until it finally moves into the first FIFO of the chain. Each time a free location is created in one FIFO of the chain, that FIFO's IR line goes LOW, enabling the preceding FIFO to write a word to fill it.

For a full expansion configuration, the amount of time it takes for IR of the first FIFO in the chain to go LOW after a word has been read from the last FIFO is the sum of the delays for each individual FIFO:

\[(N - 1) \times (3 \times \text{transfer clock}) + 2 \times \text{TWCLK}\]

where \(N\) is the number of FIFOs in the expansion and TWCLK is the WCLK period. Note that extra cycles should be added for the possibility that the tSKEW1 specification is not met between RCLK and transfer clock, or WCLK and transfer clock, for the IR flag.

The Transfer Clock line should be tied to either WCLK or RCLK, whichever is faster. Both these actions result in data moving, as quickly as possible, to the end of the chain and free locations to the beginning of the chain.

DIFFERENCES BETWEEN THE IDT72V261LA/72V271LA AND IDT72V261L/72V271L

IDT has improved the performance of the IDT72V261/72V271 SuperSync™ FIFOs. The new versions are designated by the “LA” mark. The LA part is pin-for-pin compatible with the original “L” version. Some differences exist between the two versions. The following table details these differences.

NOTES:
1. WCLK and RCLK can vary independently and can be stopped. There is no restriction on operating WCLK and RCLK.
2. This is TSKEW3.
3. Tf is the period of the ‘selected clock’.
4. TRCLK is the cycle period of the read clock.
5. Typical ICC1 is based on VCC = 3.3V, TA = 25°C, fS = WCLK frequency = RCLK frequency (in MHz using TTL levels), data switching at fS/2, CL = Capacitive Load (in pF).
