Highlights

• Synchronous Equipment Timing Source (SETS) for Synchronous Ethernet (SyncE) per ITU-T G.8264
• DPLL1 generates ITU-T G.8262 compliant SyncE clocks, Telcordia GR-1244-CORE/GR-253-CORE, and ITU-T G.813 compliant SONET/SDH clocks
• DPLL2 performs rate conversions for synchronization interfaces or for other general purpose timing applications
• DPLL1 can be configured as a Digitally Controlled Oscillators (DCOs) for PTP clock synthesis
• DCO frequency resolution is [(77760 / 1638400) * 2^48] or ~1.686305041e-10 ppm
• APLL1 and APLL2 generate clocks with jitter < 1 ps RMS (12 kHz to 20 MHz) for: 1000BASE-T and 1000BASE-X
• Fractional-N input dividers support a wide range of reference frequencies
• Locks to 1 Pulse Per Second (PPS) references
• DPLLs, APLL1 and APLL2 can be configured from an external EEPROM after reset

Features

• Differential reference inputs (IN1 to IN4) accept clock frequencies between 1 PPS and 650 MHz
• Single ended inputs (IN5 to IN6) accept reference clock frequencies between 1 PPS and 162.5 MHz
• Loss of Signal (LOS) pins (LOS0 to LOS3) can be assigned to any clock reference input
• Reference monitors qualify/disqualify references depending on activity, frequency and LOS pins
• Automatic reference selection state machines select the active reference for each DPLL based on the reference monitors, priority tables, revertive and non-revertive settings and other programmable settings
• Fractional-N input dividers enable the DPLLs to lock to a wide range of reference clock frequencies including: 10/100/1000 Ethernet, 10G Ethernet, OTN, SONET/SDH, PDH, TDM, GSM, CPRI, and GNSS frequencies
• Any reference inputs (IN1 to IN6) can be designated as external sync pulse inputs (1 PPS, 2 kHz, 4 kHz or 8 kHz) associated with a selectable reference clock input
• FSYNC_8K_1PPS and MFSYNC_2K_1PPS output sync pulses that are aligned with the selected external input sync pulse input and frequency locked to the associated reference clock input
• DPLL1 can be configured with bandwidths between 0.09 mHz and 567 Hz
• DPLL1 locks to input references with bandwidths between 1 PPS and 650 MHz
• DPLL2 locks to input references with frequencies between 1 PPS and 650 MHz
• DPLL1 complies with ITU-T G.8262 for Synchronous Ethernet Equipment Clock (EEC), and G.813 for Synchronous Equipment Clock (SEC); and Telcordia GR-253-CORE/GR-1244-CORE for Stratum 3 and SONET Minimum Clock (SMC)
• DPLL1 generates clocks with PDH, TDM, GSM, CPRI/OBSAI, 10/100/1000 Ethernet and GNSS frequencies; these clocks are directly available on OUT1 and OUT8
• DPLL2 generates N x 8 kHz clocks up to 100 MHz that are output on OUT9 and OUT10
• APLL1 and APLL2 are connected to DPLL1
• APLL1 and APLL2 generate 10/100/1000 Ethernet, 10G Ethernet, or SONET/SDH frequencies
• Any of eight common TCXO/OCXO frequencies can be used for the System Clock: 10 MHz, 12.8 MHz, 13 MHz, 19.44 MHz, 20 MHz, 24.576 MHz, 25 MHz or 30.72 MHz
• The I2C slave, SPI or the UART interface can be used by a host processor to access the control and status registers
• The I2C master interface can automatically load a device configuration from an external EEPROM after reset
• Differential outputs OUT3 to OUT6 output clocks with frequencies between 1 PPS and 650 MHz
• Single ended outputs OUT1, OUT2, OUT7 and OUT8 output clocks with frequencies between 1 PPS and 125 MHz
• Single ended outputs OUT9 and OUT10 output clocks N*8 kHz multiples up to 100 MHz
• DPLL1 supports independent programmable delays for each of IN1 to IN6; the delay for each input is programmable in steps of 0.61 ns with a range of ±78 ns
• The input to output phase delay of DPLL1 is programmable in steps of 0.0745 ps with a total range of ±20 μs
• The clock phase of each of the output dividers for OUT1 (from APLL1) to OUT8 is individually programmable in steps of ~200 ps with a total range of +/-180°
• 1149.1 JTAG Boundary Scan
• 72-QFN green package

Applications

• Access routers, edge routers, core routers
• Carrier Ethernet switches
• Multi-service access platforms
• PON OLT
• LTE eNodeB
• ITU-T G.8264 Synchronous Equipment Timing Source (SETS)
• ITU-T G.8262 Synchronous Ethernet Equipment Clock (EEC)
• ITU-T G.813 Synchronous Equipment Clock (SEC)
• Telcordia GR-253-CORE/GR1244-CORE Stratum 3 Clock (S3) and SONET Minimum Clock (SMC)
The 82P33714 Synchronous Equipment Timing Source (SETS) for Synchronous Ethernet (SyncE) provides tools to manage timing references, clock generation and timing paths for SyncE based clocks, per ITU-T G.8264 and ITU-T G.8262. 82P33714 meets the requirements of ITU-T G.8262 for synchronous Ethernet Equipment Clocks (EECs) and ITU-T G.813 for Synchronous Equipment Clocks (SEC). The device outputs low-jitter clocks that can directly synchronize Ethernet interfaces; as well as SONET/SDH and PDH interfaces.

The 82P33714 accepts four differential reference inputs and two single ended reference inputs that can operate at common GNSS, Ethernet, SONET/SDH and PDH frequencies that range from 1 Pulse Per Second (PPS) to 650 MHz. The references are continually monitored for loss of signal and for frequency offset per user programmed thresholds. All of the references are available to both Digital PLLs (DPLLs). The active reference for each DPLL is determined by forced selection or by automatic selection based on user programmed priorities and locking allowances and based on the reference monitors and LOS inputs.

The 82P33714 can accept a clock reference and an associated phase locked sync signal as a pair. DPLL1 can lock to the clock reference and align the frame sync and multi-frame sync outputs with the paired sync input. The device allows any of the differential or single ended reference inputs to be configured as sync inputs that can be associated with any of the other differential or single ended reference inputs. The input sync signals can have a frequency of 1 PPS, 2 kHz, 4 kHz or 8 kHz. This feature enables DPLL1 to phase align its frame sync and multi-frame sync outputs with a sync input without the need use a low bandwidth setting to lock directly to the sync input.

The DPLLs support three primary operating modes: Free-Run, Locked and Holdover. In Free-Run mode the DPLLs synthesize clocks based on the system clock alone. In Locked mode the DPLLs filter reference clock jitter with the selected bandwidth. In Locked mode, the long-term output frequency accuracy is the same as the long term frequency accuracy of the selected input reference. In Holdover mode, the DPLL uses frequency data acquired while in Locked mode to generate accurate frequencies when input references are not available.

DPLL1 also supports DCO mode. In DCO mode the DPLL control loop is opened and the DCO can be controlled by an IEEE 1588 clock recovery servo running on an external processor to synthesize IEEE 1588 clocks.

The 82P33714 requires a system clock for its reference monitors and other digital circuitry. The frequency accuracy of the system clock determines the frequency accuracy of the DPLLs in Free-Run mode. The frequency stability of the system clock determines the frequency stability of the DPLLs in Free-Run mode and in Holdover mode; and it affects the wander generation of the DPLLs in Locked mode.

When used with a suitable system clock, DPLL1 meets the frequency accuracy, pull-in, hold-in, pullout, noise generation, noise tolerance, transient response, and holdover performance requirements of the following applications: ITU-T G.8262/G.813 EEC/SEC options 1 and 2, Telcordia GR-1244 Stratum 3 (S3), Telcordia GR-253-CORE S3 and SONET Minimum Clock (SMC).

DPLL1 can be configured with a range of selectable filtering bandwidths from 0.09 MHz to 567 Hz. The 17 MHz bandwidth can be used to lock the DPLL directly to a 1 PPS reference. The 92 MHz bandwidth can be used for G.8262/G.813 Option 2, or Telcordia GR-253-CORE S3, or SMC applications. The bandwidths in the range 1.1 Hz to 8.9 Hz can be used for G.8262/G.813 Option 1 applications. The bandwidth of 1.1 Hz or 2.2 Hz can be used for Telcordia GR-1244-CORE S3 applications. Bandwidths above 10 Hz can be used in jitter attenuation and rate conversion applications.

DPLL2 is a wideband (BW > 25Hz) frequency translator that can be used, for example, to convert a recovered line clock to a 1.544 MHz or 2.048 MHz synchronization interface clock.

For SETS applications per ITU-T G.8264, DPLL1 is configured as an EEC/SEC to output clocks for the T0 reference point and DPLL2 is used to output clocks for the T4 reference point.

Clocks generated by DPLL1 can be passed through APLL1 or APLL2 which are LC based jitter attenuating Analog PLLs (APLLs). The output clocks generated by APLL1 and APLL2 are suitable for serial GbE and lower rate interfaces.

All 82P33714 control and status registers are accessed through an I2C slave, SPI or UART interface. For configuring the DPLLs, APLL1 and APLL2, the I2C master interface can automatically load a configuration from an external EEPROM after reset.

</table>
| 6       | OSCI     | I   | CMOS     | **Global Control Signal**
|         |          |     |          | **OSCI**: Crystal Oscillator System Clock
|         |          |     |          | A clock provided by a crystal oscillator is input on this pin. It is the system clock for the device. The oscillator frequency is selected via pins XO_FREQ0 ~ XO_FREQ2. |
| 58      | MS/SL    | I   | CMOS     | **MS/SL**: Master / Slave Selection
|         |          |     |          | This pin, together with the MS_SL_CTRL bit, controls whether the device is configured as the Master or as the Slave. The signal level on this pin is reflected by the MASTER_SLAVE bit.
|         |          |     |          | MS_SL = 0: Slave
|         |          |     |          | MS_SL = 1: Master (default with internal pull-up) |
| 59      | SONET/SDH/LOS3 | I  | CMOS     | **SONET/SDH**: SONET / SDH Frequency Selection
|         |          |     |          | During reset, this pin determines the default value of the IN_SONET_SDH bit:
|         |          |     |          | High: The default value of the IN_SONET_SDH bit is ‘1’ (SONET);
|         |          |     |          | Low: The default value of the IN_SONET_SDH bit is ‘0’ (SDH).
|         |          |     |          | After reset, the value on this pin takes no effect. LOS3- This pin is used to disqualify input clocks. See input clocks section for more details. |
| 52      | RSTB     | I   | CMOS     | **RSTB**: Reset
|         |          |     |          | Refer to section 2.2 reset operation for details. |
| 7 8 9   | XO_FREQ0/LOS0/LOS1/LOS2 | I  | CMOS     | **XO_FREQ0 ~ XO_FREQ2**: These pins set the oscillator frequency.
|         |          |     |          | XO_FREQ[2:0] Oscillator Frequency (MHz)
|         |          |     |          | 000 10.000
|         |          |     |          | 001 12.800
|         |          |     |          | 010 13.000
|         |          |     |          | 011 19.440
|         |          |     |          | 100 20.000
|         |          |     |          | 101 24.576
|         |          |     |          | 110 25.000
|         |          |     |          | 111 30.720
|         |          |     |          | LOS0 ~ LOS2 - These pins are used to disqualify input clocks. See input clocks section for more details. After reset, this pin takes on the operation of LOS0-LOS2. |
| 31 32   | IN1_POS/IN1_NEG | I  | PECL/LVDS | **IN1_POS / IN1_NEG**: Positive / Negative Input Clock 1
|         |          |     |          | A reference clock is input on this pin. This pin can also be used as a sync input, and in this case a 2 kHz, 4 kHz, 8 kHz, or 1PPS signal can be input on this pin. |
| 33 34   | IN2_POS/IN2_NEG | I  | PECL/LVDS | **IN2_POS / IN2_NEG**: Positive / Negative Input Clock 1
|         |          |     |          | A reference clock is input on this pin. This pin can also be used as a sync input, and in this case a 2 kHz, 4 kHz, 8 kHz, or 1PPS signal can be input on this pin. |
| 35 36   | IN3_POS/IN3_NEG | I  | PECL/LVDS | **IN3_POS / IN3_NEG**: Positive / Negative Input Clock 3
|         |          |     |          | A reference clock is input on this pin. This pin can also be used as a sync input, and in this case a 2 kHz, 4 kHz, 8 kHz, or 1PPS signal can be input on this pin. |
| 38 39   | IN4_POS/IN4_NEG | I  | PECL/LVDS | **IN4_POS / IN4_NEG**: Positive / Negative Input Clock 4
|         |          |     |          | A reference clock is input on this pin. This pin can also be used as a sync input, and in this case a 2 kHz, 4 kHz, 8 kHz, or 1PPS signal can be input on this pin. |
| 37      | IN5      | I   | CMOS     | **IN5**: Input Clock 5
|         |          |     |          | A reference clock is input on this pin. This pin can also be used as a sync input, and in this case a 2 kHz, 4 kHz, 8 kHz, or 1PPS signal can be input on this pin. |
| 41      | IN6      | I   | CMOS     | **IN6**: Input Clock 6
|         |          |     |          | A reference clock is input on this pin. This pin can also be used as a sync input, and in this case a 2 kHz, 4 kHz, 8 kHz, or 1PPS signal can be input on this pin. |

         |       |          |          | The test data are input on this pin. They are clocked into the device on the rising edge of TCK. |
2.1 RECOMMENDATIONS FOR UNUSED INPUT AND OUTPUT PINS

2.1.1 INPUTS

Control Pins
All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A 1kΩ resistor can be used.

Single-Ended Clock Inputs
For protection, unused single-ended clock inputs should be tied to ground.

Differential Clock Inputs
For applications not requiring the use of a differential input, both _POS and _NEG can be left floating. Though not required, but for additional protection, a 1kΩ resistor can be tied from _POS to ground.

2.1.2 OUTPUTS

Status Pins
For applications not requiring the use of a status pin, we recommend bringing out to a test point for debugging purposes.

Single-Ended Clock Outputs
All unused single-ended clock outputs can be left floating, or can be brought out to a test point for debugging purposes.

Differential Clock Outputs
All unused differential outputs can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.

2.2 RESET OPERATION

The device must be reset properly in order to ensure operations conform with specification.

To properly reset the device, the RSTB pin must be held at a low value for at least 50 usec. The device should be brought out of reset only at the time when power supplies are stabilized and the system clock is available on OSCi pin. The RSTB can be held low until this time, or pulsed low for at least 50us after this time.

The bootstrap pins (XO_FREQ[2:0], MPU_MODE[1:0], I2C_AD[2:0], MS/SL, SONET/SDH) need to be held at desired states for at least 2ms after de-assertion of RSTB pin to allow correct sampling. See Figure 3 for detail.

If loading from an EEPROM, the maximum time from RSTB de-assert to have stable clocks is 100ms. Note that if there is a bad EEPROM read sequence and the EEPROM loading is repeated once or twice (three times halts the device), then this time can be 2 or 3 times longer respectively. If not loading from EEPROM the maximum time from RSTB de-assert to have stable clocks is 10ms.

An on-board reset circuit or a commercially available voltage supervisory can be used to generate the reset signal. It is also feasible to use a standalone power-up RC reset circuit. When using a power-up RC reset circuit, careful consideration must be taken into account to fine tune the circuit properly based on each power supply's specification to ensure the power supply rise time is fast enough with respect to the RC time constant of the RC circuit.
2.3 MS/SL PIN USAGE

The MS/SL pin is used for timing card redundancy applications where there is a primary and secondary timing card in the system. For other applications, this pin should be left unconnected or connected to an external pull-up.

For more information, see AN-901, How to Implement Master/Slave for SETS and SMU Devices on Timing Redundancy Designs.
3 FUNCTIONAL DESCRIPTION

3.1 SYNCHRONOUS ETHERNET, SONET, AND SDH ARCHITECTURE

82P33714 integrates key features that allow the device to be used in Synchronous Ethernet, SONET and SDH applications. There are several key synchronization standards that are important to meet for such a system, they are:

- ITU-T Recommendation G.8262, Timing characteristics of Synchronous Ethernet Equipment slave clock (EEC)
- ITU-T Recommendation G.8264, Distribution of timing through packet networks
- ITU-T Recommendation G.812, Timing requirements of slave clocks suitable for use as node clocks in synchronization networks.
- GR-253-CORE - Telcordia Technologies Generic Requirements - Issue 5, October 2009
- GR-1244-CORE - Telcordia Technologies Generic Requirements - Issue 4, October 2009
- ATIS-0900101.2006 - T1.101 - Synchronization Interface Standard

Figure 3 shows a single blade architecture that it is usually used in simple equipment.

**Figure 3. SyncE/SONET/SDH single blade application**

Figure 4 shows an active/redundant architecture, as described before it is usually used in Telecom equipment that are designed to have a redundant timing card in case of primary timing card failure. The redundant timing card mimics the output of the active timing card, so in case of failure the system will still provide proper synchronization.
Figure 4. SyncE/SONET/SDH active/redundant application
3.2 HARDWARE FUNCTIONAL DESCRIPTION

3.2.1 SYSTEM CLOCK

A crystal oscillator should be used as an input on the OSCI pin. This clock is provided for the device as a system clock. The system clock is used as a reference clock for all the internal circuits. The active edge of the system clock can be selected by the OSC_EDGE bit in xo_freq_cnfg register.

Eight common oscillator frequencies can be used for the stable System Clock. The oscillator frequency can be set by pins or by xo_freq_cnfg register as shown in Table 2.

Table 2: Oscillator Frequencies

<table>
<thead>
<tr>
<th>xo_freq[2:0] pins</th>

<td>30.720</td>
</tr>
</tbody>
</table>

An offset from the nominal frequency may be compensated by setting the NOMINAL_FREQ_VALUE[23:0] bits. The calibration range is within ±741 ppm.

The crystal oscillator should be chosen accordingly to meet different applications and standard requirements. (See AN-807 Recommended Crystal Oscillators for NetSynchro WAN PLL).

3.2.2 MODES OF OPERATION

3.2.2.1 DPLL1 Operating Mode

The DPLL1 can operate in several different modes as shown in Table 3.

The DPLL1 operating mode is controlled by the DPLL1_OPERATING_MODE[4:0] bits.

Table 3: DPLL1 Operating Mode Control

</tbody>
</table>

When the operating mode is switched automatically, the operation of the internal state machine is shown in Figure 5.

Whether the operating mode is under external control or is switched automatically, the current operating mode is always indicated by the DPLL1_OPERATING_STS[4:0] bits. When the operating mode switches, the DPLL1_OPERATING_STS bit will be set. If the DPLL1_OPERATING_STS bit is ‘1’, an interrupt will be generated if the corresponding mask bit is set to “1”, the mask bit is set to “0” by default.
Notes to Figure 5:
1. Reset.
2. An input clock is selected.
3. The DPLL selected input clock is disqualified AND No qualified input clock is available.
4. The DPLL selected input clock is switched to another one.
5. The DPLL selected input clock is locked (the DPLL_LOCK bit is ‘1’).
6. The DPLL selected input clock is disqualified AND No qualified input clock is available.
7. The DPLL selected input clock is unlocked (the DPLL_LOCK bit is ‘0’).
8. The DPLL selected input clock is locked again (the DPLL_LOCK bit is ‘1’).
9. The DPLL selected input clock is switched to another one.
10. The DPLL selected input clock is locked (the DPLL_LOCK bit is ‘1’).
11. The DPLL selected input clock is disqualified AND No qualified input clock is available.
12. The DPLL selected input clock is switched to another one.
13. The DPLL selected input clock is disqualified AND No qualified input clock is available.
14. An input clock is selected.
15. The DPLL selected input clock is switched to another one.

The causes of Item 4, 9, 12, 15 - ‘the DPLL selected input clock is switched to another one’ - are: (The DPLL selected input clock is disqualified AND Another input clock is switched to) OR (In Revertive switching, a qualified input clock with a higher priority is switched to) OR (The DPLL selected input clock is switched to another one Forced selection).
3.2.2.1 Free-Run Mode

In Free-Run mode, the DPLL1 output refers to the system clock and is not affected by any input clock. The accuracy of the DPLL1 output is equal to that of the system clock.

3.2.2.1.2 Pre-Locked Mode

In Pre-Locked mode, the DPLL1 output attempts to track the selected input clock.

The Pre-Locked mode is a secondary, temporary mode.

3.2.2.1.3 Locked Mode

In Locked mode, the DPLL1 is locked to the input clock. The phase and frequency offset of the DPLL1 output track those of the DPLL1 selected input clock.

For a closed loop, different bandwidths and damping factors can be used depending on DPLL locking stages: starting, acquisition and locked.

In the first two seconds when the DPLL1 attempts to lock to the selected input clock, the starting bandwidth and damping factor are used. They are set by the DPLL1_START_BW[4:0] bits and the DPLL1_START_DAMPING[2:0] bits respectively.

During the acquisition, the acquisition bandwidth and damping factor are used. They are set by the DPLL1_ACQ_BW[4:0] bits and the DPLL1_ACQ_DAMPING[2:0] bits respectively.

When the DPLL1 is locked, the locked bandwidth and damping factor are used. They are set by the DPLL1_LOCKED_BW[4:0] bits and the DPLL1_LOCKED_DAMPING[2:0] bits respectively.

The corresponding bandwidth and damping factor are used when the DPLL1 operates in different locking stages: starting, acquisition and locked, as controlled by the device automatically.

The locked bandwidth is selectable can be set as shown in Table 4.

</table>
3.2.2.1.4 Pre-Locked2 Mode

In Pre-Locked2 mode, the DPLL1 output attempts to track the selected input clock.

The Pre-Locked2 mode is a secondary, temporary mode.

3.2.2.1.5 Lost-Phase Mode

In Lost-Phase mode, the DPLL1 output attempts to track the selected input clock.

The Lost-Phase mode is a secondary, temporary mode.

3.2.2.1.6 DCO control modes

Figure 6 show a high level diagram of the DCO control architecture, it shows the DCO in DPLL1 being controlled. The DCO is a phase accumulator running at an internal clock. The DCO is controlled by a digital word that can represent phase offset or frequency offset. In the case of an IEEE 1588 application, the external processor will run the clock recovery servo algorithm and it will generate a frequency offset word to control the DCO.

The DCO control modes can be set by registers DPLL1_operating_mode_cfg for DPLL1.

Figure 6 shows the DCO being controlled by writing a frequency offset word into the DCO, then by changing temporarily the DCO’s frequency, the phase of the clock (or 1PPS) being generated by the DCO will also change. The output phase change is the product of the frequency change times the duration for which the frequency change is applied for. Because the DCO’s frequency word has a very fine resolution, the output phase can be adjusted in very fine steps. In this case the clock recovery servo algorithm controls the bandwidth and phase slope limiting. The frequency offset word can be written into DPLL1_holdover_freq_cnfg[39:0] bits of frequency configuration registers for DPLL12. This value is 2’s complement signed number. Total range is +/-92 ppm, and the DCO programming resolution is $[(77760 / 1638400) * 2^{-48}]$ or $\approx 1.686305041e^{-10}$ ppm. The DCO resolution is affected by the offset applied into the DCO, so when writing into the DCO, the programming resolution is $[(77760/1638400) * 2^{-48}] * (1 + offset-in-ppm / 1e6)$.

Controlling the DCO’s frequency for smaller fine resolution phase changes is a good method, but for bigger phase changes it is better to use the snap-alignment method. The snap phase alignment is fast but only provides coarse adjustment. The 82P33714 allows for both the fine phase adjustment by controlling the frequency of the DCO and the coarse phase adjustment by snap-aligning the output clock (or 1PPS), for details, see section 3.2.7.3 Output Phase control on page 31.

3.2.2.1.7 Holdover Mode

In Holdover mode, the DPLL1 resorts to the stored frequency data acquired in Locked mode to control its output. The DPLL1 output is not phase locked to any input clock. The frequency offset acquiring method is selected by the man_holdover bit, auto_avg bit, the hist_mode[1:0] bits, and the avg_mode[1:0] bits in DPLL1_holdover_mode_cfg registers as shown in Table 5.
The default value for holdover mode is set to current averaged value with holdover filter BW of ~1.5mHz. In this mode the initial frequency offset is better than 1.1e-5ppm assuming that there is no in-band jitter/wander at the input just before entering holdover state. The default mode is used for Telcordia GR-1244, Telcordia GR-253, ITU-T G.8262 and ITU-T G.813 to meet holdover requirements.

In Manual Mode, the frequency offset is set by the DPLL1_holdover_freq_cnfg[39:0] bits. The accuracy is 1.686305041e-10 ppm, however the resolution is affected by the frequency offset applied, so when writing the frequency offset, the programming resolution is \((77760/1638400) \times 2^{-48}\) * (1 + offset-in-ppm / 1e6).

The offset value, which is acquired by the modes shown in Table 5, can be read from the holdover_freq_cnfg[39:0] bits by setting the read_avg bit to “1”. If read_avg bit is set to “0” then the value in holdover_freq_cnfg[39:0] bits is the value written into it. The value is 2’s complement signed number, and the total range is +/- 92 ppm.

The holdover frequency resolution is calculated as follows:

\[
\text{Holdover Frequency resolution: } \text{HO}_\text{freq}\_\text{res} = \left(\frac{77760}{1638400}\right) \times 2^{-48}
\]

The Holdover value read from register bits holdover_freq_cnfg[39:0] must be converted to decimal:

\[
\text{HO}_\text{value}\_\text{dec} = \text{holdover_freq_cnfg[39:0]} \text{ value in decimal}
\]

The frequency offset in ppm is calculated as follows:

\[
\text{Holdover Frequency Offset (ppm)} = \left(\frac{\text{HO}_\text{freq}\_\text{res} \times \text{HO}_\text{value}\_\text{dec}}{1-(\text{HO}_\text{freq}\_\text{res} \times \text{HO}_\text{value}\_\text{dec})/166}\right)
\]

#### 3.2.2.1.8 Hitless Reference Switching

Bit hitless_switch_en in DPLL1_mon_sw_pbo_cnfg register can be used to set hitless reference switching. When a Hitless Switching (HS) event is triggered, the phase offset of the selected input clock with respect to the DPLL1 output is measured. The device then automatically accounts for the measured phase offset and compensates for the appropriate phase offset into the DPLL output so that the phase transients on the DPLL1 output are minimized. The input frequencies should be set to frequencies equal to 8 kHz or higher.

If hitless_switch_en is set to “1”, a HS event is triggered if any one of the following conditions occurs:

- DPLL1 selected input clock switches to a different reference
- DPLL1 exits from Holdover mode or Free-Run mode

For the two conditions, the phase transients on the DPLL1 output are minimized to be no more than 0.61 ns with HS. The HS can also be frozen at the current phase offset by setting the hitless_switch_freeze bit in DPLL1_mon_sw_pbo_cnfg register. When the HS is frozen, the device will ignore any further HS events triggered by the above two conditions, and maintain the current phase offset.

When the HS is disabled, there may be a phase shift on the DPLL1 output, as the DPLL1 output tracks back to 0 degree phase offset with respect to the DPLL1 selected input clock. This phase shift can be limited; see section 3.2.2.1.9 Phase Slope Limit.
3.2.2.1.9 Phase Slope Limit

To meet the phase slope requirements of Telcordia and new ITU-T standards, both DPLL1 provides a phase slope limiting feature to limit the rate of output phase movement. The limit level is selectable via DPLL1_ph_limit[2:0] bits in DPLL1_bw_overshoot_cfg register. The options are shown in Table 6.

Table 6: DPLL1 Phase Slope Limit

</tbody>
</table>

*Note: The default phase slope limiting is set to programmable with a default value set to 0 ns/s, therefore the phase slope limiting must be set to the proper value to meet different standards according to this table.

The programmable phase slope limiting can be set by writing into registers DPLL1_prog_ph_limit_cfg[23:0]. The range of the programmable limit is 1484.3614 us/s.

3.2.2.1.10 Frequency Offset Limit

The DPLL1 output is limited to be within the programmed DPLL hard limit (refer to Chapter 3.2.4.3).

3.2.2.2 DPLL2 Operating Mode

The DPLL2 operating mode is controlled by the DPLL2_OPERATING_MODE[2:0] bits, as shown in Table 7. DPLL2 is disabled by default, write “0” to bit DPLL2_pdn in pdn_conf register to enable it.

Table 7: DPLL2 Operating Mode Control

</tbody>
</table>

When the operating mode is switched automatically, the operation of the internal state machine is shown in Figure 7:

![Figure 7. DPLL2 Automatic Operating Mode](image)

Notes to Figure 7:
1. Reset.
2. An input clock is selected.
3. (The DPLL2 selected input clock is disqualified) OR (A qualified input clock with a higher priority is switched to) OR (The DPLL2 selected input clock is switched to another one by Forced selection).
4. An input clock is selected.
5. No input clock is selected.

3.2.2.2.1 Free-Run Mode

In Free-Run mode, the DPLL2 output refers to the system clock and is not affected by any input clock. The accuracy of the DPLL2 output is equal to that of the system clock.

3.2.2.2.2 Locked Mode

In Locked mode, the DPLL2 is locked to the input clock. The phase and frequency offset of the DPLL2 output track those of the DPLL2 selected input clock.

DPLL2 is a wide BW DPLL, with loop bandwidth higher than 25Hz.
3.2.2.2.3 Holdover Mode

In Holdover mode, the DPLL2 has 2 modes of operation for the holdover set by DPLL2_auto_avg bit in DPLL2_holdover_mode_config register.

DPLL2_auto_avg = 0: holdover frequency is the instantaneous value of integral path just before entering holdover. If the DPLL2 was locked to an input clock reference that has no in-band jitter/wander and was then manually set to go into holdover, the initial frequency accuracy is 4.4X10^-8 ppm.

DPLL2_auto_avg = 1: averaged frequency value is used as holdover frequency. The holdover average bandwidth is about 1.5mHz. In this mode the initial frequency offset is 1.1e-5ppm assuming that there is no in-band jitter/wander at the input just before entering holdover state.

3.2.2.2.4 Frequency Offset Limit

The DPLL2 output is limited to be within the DPLL hard limit (refer to Chapter 3.2.4.3).

3.2.3 INPUT CLOCKS AND FRAME SYNC

The 82P33714 has 6 input clocks that can also be used for frame sync pulses.

</table>

Each Pre-divider consists of an FEC divider and a DivN divider. IN1–IN4 also include an HF (High Frequency) divider. Figure 8 shows a block diagram of the pre-dividers for an input clock.

For 1 PPS, 2 kHz, 4 kHz or 8 kHz input clock frequency only, the Pre-divider should be bypassed by setting INn_DIV[1:0] bits = “0” (1 ≤ n ≤ 4), DIRECT_DIV bit = “0”, and LOCK_8K bit = “0”. The corresponding IN_FREQ[3:0] bits should be set to match the input frequency.

The HF divider, which is available for IN1 ~ IN4, should be used when the input clock is higher than (> ) 162.5 MHz. The input clock can be divided by 4, 5 or can bypass the HF divider, as determined by the INn_DIV[1:0] bits (1 ≤ n ≤ 4).

The DivN divider can be bypassed, as determined by the DIRECT_DIV bit and the LOCK_8K bit. When DivN divider is bypassed, the corresponding IN_FREQ[3:0] bits should be set to match the input frequency. DivN must be bypassed on a reference clock input that is also associated with another reference input used as SYNC.

When the DivN divider is used for INn (1 ≤ n ≤ 6), the division factor setting should observe the following order:
1. Write the lower eight bits of the division factor to the PRE_DIVN_VALUE[7:0] bits;
2. Write the higher eight bits of the division factor to the PRE_DIVN_VALUE[14:8] bits.

The division factor is calculated as follows:
Division Factor = (the frequency of the clock input to the DivN divider ÷ the frequency of the DPLL required clock set by the IN_FREQ[3:0] bits) - 1

The Pre-divider configuration and the division factor setting depend on the input clock on one of the IN1 ~ IN6 pins and the DPLL required clock.

For the fractional input divider, the FEC divider, each input clock has a 16-bit (fec_divp_config[15:0]) that represents the value of the numerator and a 16-bit (fec_divq_config[15:0]) that represents the value of the numerator.
The denominator of FEC divider. The FEC division factor is calculated as follows:

\[
\text{FEC Division Factor} = \frac{\text{fec\_divp\_cnfg}[15:0]}{\text{fec\_divq\_cnfg}[15:0]}
\]

Figure 8. Pre-divider for an input clock
3.2.3.2 Input Clock Quality Monitoring

The qualities of all the input clocks are always monitored in the following aspects:
- Activity
- Frequency

Activity and frequency monitoring are conducted on all the input clocks.

The qualified clocks are available for selection for the 2 DPLLs.

3.2.3.2.1 Activity Monitoring

Activity is monitored by using an internal leaky bucket accumulator, as shown in Figure 9.

Each input clock is assigned an internal leaky bucket accumulator. The input clock is monitored for each period of 128 ms, the internal leaky bucket accumulator is increased by 1 when an event is detected; and it is decreased by 1 when no event is detected within the period set by the decay rate. The event is that an input clock drifts outside \( \pm 500 \text{ ppm} \) with respect to the system clock within a 128 ms period.

There are four configurations (0 - 3) for a leaky bucket accumulator. The leaky bucket configuration for an input clock is selected by the corresponding BUCKET_SEL[1:0] bits. Each leaky bucket configuration consists of four elements: upper threshold, lower threshold, bucket size and decay rate.

The bucket size is the capability of the accumulator. If the number of the accumulated events reach the bucket size, the accumulator will stop increasing even if further events are detected. The upper threshold is a point above which a no-activity alarm is raised. The lower threshold is a point below which the no-activity alarm is cleared. The decay rate is a certain period during which the accumulator decreases by 1 if no event is detected.

The leaky bucket configuration is programmed by one of four groups of register bits: the BUCKET_SIZE_n_DATA[7:0] bits, the UPPER_THRESHOLD_n_DATA[7:0] bits, the LOWER_THRESHOLD_n_DATA[7:0] bits and the DECAY_RATE_n_DATA[1:0] bits respectively; ‘n’ is 0 ~ 3.

The no-activity alarm status of the input clock is indicated by the INn_NO_ACTIVITY_ALARM bit (6 ≥ n ≥ 1).

The input clock with a no-activity alarm is disqualified for clock selection for the DPLLs.

---

**Figure 9. Input Clock Activity Monitoring**

![Diagram of Input Clock Activity Monitoring](image-url)
3.2.3.2.2 Frequency Monitoring

Frequency is monitored by comparing the input clock with a reference clock. The reference clock can be derived from the system clock or the output of DPLL1, as determined by the FREQ_MON_CLK bit.

Each reference clock has a hard frequency monitor and a soft frequency monitor. Both monitors have two thresholds, rejecting threshold and accepting threshold, which are set in HARD_FREQ_MON_THRESHOLD[7:0] and SOFT_FREQ_MON_THRESHOLD[7:0]. So four frequency alarm thresholds are set for frequency monitoring: Hard Alarm Accepting Threshold, Hard Alarm Rejecting Threshold, Soft Alarm Accepting Threshold and Soft Alarm Rejecting Threshold.

The frequency hard alarm accepting threshold can be calculated as follows:

\[
\text{Frequency Hard Alarm Accepting Threshold (ppm)} = (\text{HARD_FREQ_MON_THRESHOLD}[7:4] + 1) \times \text{FREQ_MON_FACTOR}[3:0] \quad (b3~0, \text{FREQ_MON_FACTOR_CNFG})
\]

The frequency hard alarm rejecting threshold can be calculated as follows:

\[
\text{Frequency Hard Alarm Rejecting Threshold (ppm)} = (\text{HARD_FREQ_MON_THRESHOLD}[3:0] + 1) \times \text{FREQ_MON_FACTOR}[3:0] \quad (b3~0, \text{FREQ_MON_FACTOR_CNFG})
\]

When the input clock frequency rises to above the hard alarm rejecting threshold, the INn_FREQ_HARD_ALARM bit \((6 \geq n \geq 1)\) will alarm and indicate ‘1’. The alarm will remain until the frequency is down to below the hard alarm accepting threshold, then the INn_FREQ_HARD_ALARM bit will return to ‘0’. There is a hysteresis between frequency monitoring, refer to Figure 10.

The soft alarm is indicated by the INn_FREQ_SOFT_ALARM bit \((6 \geq n \geq 1)\) in the same way as hard alarm.

The input clock with a frequency hard alarm is disqualified for clock selection for the DPLLs, but the soft alarm doesn’t affect the clock selection for the DPLLs.

The frequency of each input clock with respect to the reference clock can be read by doing the following step:

1. Read the value in the IN_FREQ_VALUE[7:0] bits and calculate as follows:

\[
\text{Input Clock Frequency (ppm)} = \text{IN_FREQ_VALUE}[7:0] \times \text{FREQ_MON_FACTOR}[3:0]
\]

Note that the value set by the FREQ_MON_FACTOR[3:0] bits depends on the application.

3.2.3.3 Input Clock Selection

For DPLL1 and DPLL2, the DPLL1/2_INPUT_SEL[3:0] bits (register DPLL1/2_input_sel_cnfg) determine the input clock selection, as shown in Table 9:

Table 9: Input Clock Selection for DPLL1 and DPLL2

<table>
<thead>
<tr>
<th>DPLL1/2_INPUT_SEL[3:0]</th>
<th>Input Clock Selection</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>1001 ~ 1010</td>
<td>Forced selection (IN5 ~ IN6)</td>
</tr>
<tr>
<td>1011 ~ 1111</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

3.2.3.3.1 Forced Selection

In Forced selection, the selected input clock is set by the DPLL1_INP-UT_SEL[3:0] and DPLL2_INPUT_SEL[4:0] bits. The results of input clocks quality monitoring do not affect the input clock selection if Forced selection is used.

3.2.3.3.2 Automatic Selection

In Automatic selection, the input clock selection is determined by input clock being valid, priority and input clock configuration. The input clock is declared valid depending on the results of input clock quality monitoring (refer to Chapter 3.2.3.2). The input clock can be configured to be valid and therefore be allowed to participate in the locking process by setting to “0” the corresponding INn_VALID bit (6 ≥ n ≥ 1) in DPLL_remote_input_valid_cnfg register, by default all the inputs are not valid, and therefore the user must set the corresponding bit to “0” in order to allow the DPLL to lock to a particular input clock. Within all the qualified input clocks, the one with the highest priority is selected. The priority is set by the corresponding INn_SEL_PRIORITY[3:0] bits in DPLL_INn_sel_priority_cnfg (6 ≥ n ≥ 1). If more than one qualified input clock INn is available, then it is important to set appropriate priorities to the input clocks, two input clocks must not have the same priority. This process is shown in Figure 11.

Figure 11. Qualified Input Clocks for Automatic Selection

3.2.3.3.2.1 Input Clock Validation

For all the input clocks, the input is declared valid depending on the results of input clock quality monitoring (refer to Chapter 3.2.3.2). The IN_NOISE_WINDOW bit should be set to ‘1’ if any of INn_FREQ[3:0] is set for frequencies ≤ 8 kHz, by default it is set to ‘0’.

For DPLL1, the following conditions must be satisfied for the input clock to be valid; otherwise, it is invalid.

- No no-activity alarm (the INn_NO_ACTIVITY_ALARM bit is ‘0’);
- No frequency hard alarm (the INn_FREQ_HARD_ALARM bit is ‘0’);
- No phase lock alarm, i.e., the INn_PH_LOCK_ALARM bit is ‘0’;
- If the ULTR_FAST_SW bit is ‘1’, the DPLL selected input clock misses less than (<) 2 consecutive clock cycles; if the ULTR_FAST_SW bit is ‘0’, this condition is ignored;
- LOS[3:0] are not set to disqualify the input clock

For DPLL2, the following conditions must be satisfied for the input clock to be valid; otherwise, it is invalid.

- No no-activity alarm (the INn_NO_ACTIVITY_ALARM bit is ‘0’);
- No frequency hard alarm (the INn_FREQ_HARD_ALARM bit is ‘0’);
- LOS[3:0] are not set to disqualify the input clock

The INn bit (6 ≥ n ≥ 1) indicates whether or not the clock is valid. When the input clock changes from ‘valid’ to ‘invalid’, or from ‘invalid’ to ‘valid’, the INn bit will be set. If the INn bit is ‘1’, an interrupt will be generated.

When the DPLL selected input clock has failed, i.e., the selected input clock changes from ‘valid’ to ‘invalid’, the DPLL_MAIN_REF_FAILED bit will be set. If the DPLL_MAIN_REF_FAILED bit is ‘1’, an interrupt will be generated.
3.2.3.3.2 Revertive and Non-Revertive Switching

For DPLL1, Revertive and Non-Revertive switchings are supported, as selected by the REVERTIVE_MODE bit.

For DPLL2, only Revertive switching is supported.

GR-1244 defines Revertive and Non-Revertive Reference switching. In Non-Revertive switching, a switch to an alternate reference is maintained even after the original reference has recovered from the failure that caused the switch. In Revertive switching, the clock switches back to the original reference after that reference recovers from the failure, independent of the condition of the alternate reference. In Non-Revertive switching, input clock switch is minimized.

In Revertive switching, the selected input clock is switched when another qualified input clock with a higher priority than the current selected input clock is available. Therefore, if REVERTIVE_MODE bit is set to “1”, then the selected input clock is switched if any of the following is satisfied:

• the selected input clock is disqualified;
• another qualified input clock with a higher priority than the selected input clock is available.

A qualified input clock with the highest priority is selected by revertive switching. If more than one qualified input clock INn is available, then it is important to set appropriate priorities to the input clocks, two input clocks must not have the same priority.

In Non-Revertive switching, the DPLL1 selected input clock is not switched when another qualified input clock with a higher priority than the current selected input clock becomes available. In this case, the selected input clock is switched and a qualified input clock with the highest priority is selected only when the DPLL1 selected input clock is disqualified. If more than one qualified input clock INn is available, then it is important to set appropriate priorities to the input clocks, two input clocks must not have the same priority.

3.2.3.3 Selected / Qualified Input Clocks Indication

The selected input clock is indicated by the CURRENTLYSeleccioned_INPUT[3:0] bits.

When the device is configured in Automatic selection and Revertive switching is enabled, the input clock indicated by the CURRENTLYSeleccioned_INPUT[3:0] bits is the same as the one indicated by the HIGHEST_PRIORITY_VALIDATED[3:0] bits.

For proper operation COARSE_PH_LOS_LIMIT_EN must be set to 0.

3.2.3.4 Input Clock Loss of Signal

There are 4 LOS input pins (LOS[3:0]) that can be used to disqualify the input clock. If they are set high, then the associated input clock is disqualified to be used as an input clock, and therefore the DPLLs will not lock to that particular input clock.

The 4 LOS pins can be associated with any input clock by setting bits LOS_EN in INn_LOS_SYNC_CNFG (1 ≤ n ≤ 6) register. By default, the LOS pins are not associated with any input.

3.2.4 DPLL LOCKING PROCESS

The following events are always monitored for the DPLLs locking process:

• Fast Loss;
• Fine Phase Loss;
• Hard Limit Exceeding.

For proper operation, COARSE_PH_LOS_LIMIT_EN must be set to 0.

3.2.4.1 Fast Loss

A fast loss is triggered when the selected input clock misses 3 consecutive clock cycles. It is cleared once an active clock edge is detected.

For DPLL1 the occurrence of the fast loss will result in the DPLL to unlock if the FAST_LOS_SW bit is ‘1’. For DPLL2, the occurrence of the fast loss will result in the DPLL to unlock regardless of the FAST_LOS_SW bit.
3.2.4.2 Fine Phase Loss

The DPLL compares the selected input clock with the feedback signal. If the phase-compared result exceeds the fine phase limit programmed by the PH_LOS_FINE_LIMT[2:0] bits, a fine phase loss is triggered. It is cleared once the phase-compared result is within the fine phase limit.

For the greatest jitter and wander tolerance, set the PH_LOS_FINE_LIMT[2:0] to the largest value.

The occurrence of the fine phase loss will result in DPLL to unlock if the FINE_PH_LOS_LIMT_EN bit is ‘1’.

3.2.4.3 Hard Limit Exceeding

Two limits are available for this monitoring. They are DPLL soft limit and DPLL hard limit. When the frequency of the DPLL output with respect to the system clock exceeds the DPLL soft / hard limit, a DPLL soft / hard alarm will be raised; the alarm is cleared once the frequency is within the corresponding limit. The occurrence of the DPLL soft alarm does not affect the DPLL locking status. The DPLL soft alarm is indicated by the corresponding DPLL_SOFT_FREQ_ALARM bit. The occurrence of the DPLL hard alarm will result in the DPLL to unlock if the FREQ_LIMIT_PH_LOS bit is ‘1’.

The DPLL soft limit is set by the DPLL_FREQ_SOFT_LIMT[6:0] bits and can be calculated as follows:

\[
DPLL \text{ Soft Limit (ppm)} = \frac{DPLL \_FREQ \_SOFTWARE \_LIMT[6:0]}{6} \times 0.724
\]

The DPLL hard limit is set by the DPLL_FREQ_HARD_LIMT[15:0] bits and can be calculated as follows:

\[
DPLL \text{ Hard Limit (ppm)} = \frac{DPLL \_FREQ \_SOF HARD \_LIMT[15:0]}{6} \times 0.0014
\]

3.2.4.4 Locking Status

The DPLL locking status depends on the locking monitoring results. The DPLL is in locked state if none of the following events is triggered during 2 seconds; otherwise, the DPLL is unlocked.

- Fast Loss (the FAST_LOS_SW bit is ‘1’);
- Fine Phase Loss (the FINE_PH_LOS_LIMT_EN bit is ‘1’);
- DPLL Hard Alarm (the FREQ_LIMIT_PH_LOS bit is ‘1’).

If the FAST_LOS_SW bit, the COARSE_PH_LOS_LIMT_EN bit, the FINE_PH_LOS_LIMT_EN bit or the FREQ_LIMIT_PH_LOS bit is ‘0’, the DPLL will be in locked state in 2 seconds.

The DPLL locking status is indicated by the corresponding DPLL LOCK bits and by the DPLL LOCK pins.

3.2.4.5 Phase Lock Alarm

DPLL1 has a phase lock alarm that will be raised when the selected input clock can not be locked in DPLL1 within a certain period. This period can be calculated as follows:

\[
\text{Period (sec.)} = \frac{\text{TIME\_OUT\_VALUE}[5:0]}{6} \times \text{MULTI\_FACTOR}[1:0]
\]

The phase lock alarm is indicated by the corresponding INn_PH_LOCK_ALARM bit (6 \(\geq n \geq 1\)).

The phase lock alarm can be cleared, as selected by the PH_ALARM_TIMEOUT bit:

- It is cleared when a ‘1’ is written to the corresponding INn_PH_LOCK_ALARM bit;
- It is cleared after the period (= \(\text{TIME\_OUT\_VALUE}[5:0] \times \text{MULTI\_FACTOR}[1:0]\) in second) starting from the time the alarm is raised.

The selected input clock with a phase lock alarm is disqualified for the DPLL1 to lock.

Note that phase lock alarm is not available for DPLL2.

3.2.5 APLL1 AND APLL2

APLL1 and APLL2 are provided for a better jitter and wander performance of the device output clocks. The bandwidth for APLL1 and APLL2 is internally set to 22 kHz (typical).

The input of both APLLs can be derived from one of the DPLL1 outputs, as selected by the apll1_path_freq_cnfg[2:0] and apll2_path_freq_cnfg[2:0] bits respectively as shown in Table 10. APLL2 is free-running by default, after reset APLL2 should be set to be connected to DPLL1 per Table 10.

Table 10: APLL1/2 input selection

<table>
<thead>
<tr>
<th>apll1/apll2_path_freq_cnfg[2:0]</th>
<th>APLL1/2 Input Selection</th>
</tr>
</thead>
<tbody>

<tr>
<td>010</td>
<td>644.53125 MHz from DPLL1</td>
</tr>
<tr>
<td>011~1111</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

To following steps should be followed to set APLL1/APLL2 output to Ethernet LAN PHY frequencies.

To initialize the device, write into the following registers:

1. Write 0x04F4F0 to bits apll1/apll2_divn_frac_cnfg[20:0] of APLL1/APLL2 fractional feedback divider configuration register to set the fractional part of feedback divider for APLL1/APLL2
2. Write 0x0051 to bits apll1/apll2_divn_den_cnfg[15:0] of APLL1/APLL2 divisor denominator configuration register to set the denominator part of feedback divider for APLL1/APLL2
3. Write 0x0010 to bits apll1/apll2_divisor_num_cnfg[15:0] of APLL1/APLL2 divisor numerator configuration register to set the numerator part of feedback divider for APLL1/APLL2
4. Write 0x21 to bits apll1/apll2_divisor_int_cnfg[5:0] of APLL1/APLL2 divisor integer configuration register to set the integer part of feedback divider for APLL1/APLL2
5. Write 0x13356218 to bits apll1/apll2_fr_ratio_cnfg[28:0] of APLL1/APLL2 feedback divider configuration register to set the feedback divider for APLL1/APLL2
After the device has been initialized according to the steps above, follow the following steps when setting APLL1/APLL2 path to 644.53125 MHz:

- Write 1'b1 to dsm_config_en bit to enable the preset programmable feedback divider of APLL1/APLL2 configuration register
- Write the corresponding value in the apll1/apll2_path_freq_config[2:0] bits according to Table 10.

After the device has been initialized according to the steps 1 to 5 above, follow the following steps when setting APLL1/APLL2 path to 625MHz: or 622.08MHz

- Write 1'b0 to dsm_config_en bit to disable the preset programmable feedback divider of APLL1/APLL2 configuration register
- Write the corresponding value in the apll1/apll2_path_freq_config[2:0] bits according to Table 10.

### 3.2.5.1 EXTERNAL FILTER

It is recommended to use external filter component for better noise suppression. The filter components are connected to VC1 for APLL1 and VC2 APLL2. Choosing the correct external components and having a printed circuit board (PCB) layout is a key task for quality operation of the APLLs external filter option. Figure 12 shows the APLL1 and APLL2 external filter components, and Table 11 shows the recommended values for Rs, Cs and Cp. The device has been characterized using these parameters. The external loop filter components should be kept as close as possible to the device. Loop filter traces should be kept short. Other signal traces should be kept separated and not run underneath the device, and loop filter components.

3.2.6 OUTPUT CLOCKS & FRAME SYNC SIGNALS

The device supports 10 output clocks and 2 frame sync output signals.

#### 3.2.6.1 Output Clocks

OUT1 can be derived either from DPLL1 or APLL1 selected by out1_mux_config[3:0].

OUT2 ~ OUT4 can be derived from APLL1.

OUT5 ~ OUT7 can be derived from APLL2.

OUT8 can be derived either from DPLL1 or APLL2 selected by out8_mux_config[3:0].

OUT1 to OUT8 have an output divider associated with each output. The divider is composed by 2 cascaded dividers, the first divider can be programmed by writing into OUTn_DIV1_CONFIG[4:0], the second divider can be programmed by writing into OUTn_DIV2_CONFIG[26:0].

Figure 13 shows the diagram for OUT1 and OUT8 output dividers and relevant register bits.
Figure 14 shows the diagram for OUT2 to OUT7 output dividers and relevant register bits.

OUT9 and OUT10 are derived from DPLL2, there is an output divider associated with it. A GUI (Time Commander) can be used to set the following bits in the respective register that are associated with the DPLL2 dividers.

- To set the feedback divider, program DPLL2_fb_div_cfg[13:0] bits of DPLL2 feedback divider register
- To set the fractional divider, program DPLL2_divn_frac_cfg[23:0] of DPLL2 fractional divider register
- To set the denominator of the fractional divider, program DPLL2_divn_den_cfg[15:0] bits of DPLL2 fractional divider denominator register
- To set the numerator of the fractional divider, program DPLL2_divn_num_cfg[15:0] bits of DPLL2 fractional divider numerator register
- To set the integer divider, program DPLL2_int_cfg[7:0]bits of DPLL2 integer divider register

OUT1 to OUT10 output clocks can be inverted by setting OUTn_INVERT bit (0: output not inverted, 1: output inverted) in OUTn_MUX_CNFG register for (1 < n < 8), and in OUT9_CNFG and OUT10_CNFG registers for OUT9 and OUT10 respectively.

The output clocks can be squelched by setting OUTn_SQUELCH[1:0] bits (0x: no squelch, 10: squelch to ‘0’, 11: squelch to ‘1’) in OUTn_MUX_CNFG register for (1 < n < 8), and in OUT9_CNFG and OUT10_CNFG registers for OUT1 to OUT8, and OUT9 and OUT10 respectively.

OUT1 to OUT8 output clocks can be individually powered down by setting OUTn_PDN bit to ‘1’ in OUTn_MUX_CNFG register for (1 < n < 8)

82P33714 provides a variety of output frequencies from 1Hz to 650MHz.

APLL1 is always enabled and the default frequency for OUT1, OUT2, and OUT3 is respectively 25 MHz, 125 MHz, and 156.25MHz. OUT4 is squelched by default.

By default, OUT5 to OUT8 are squelched. Set the proper registers to set desired frequency values for OUT5 to OUT8.

DPLL2 is disabled by default, and if it is enabled, then the default frequency for OUT9 and OUT10 is respectively 16.384 MHz and 2.048 MHz.

APLL1, APLL2, and the DPLLs can be configured from an external EEPROM after reset. It can be used to set specific start up frequency values as needed by the application.

3.2.6.2 Frame Sync Signals

Either an 8 kHz or a 2 kHz frame sync, or a 1PPS sync signal are output on the FRSYNC_8K_1PPS and MFRSYNC_2K_1PPS pins if enabled by the 8K_1PPS_EN and 2K_1PPS_EN bits respectively. They are CMOS outputs.

The output sync frequencies are independent of the input sync frequency. The output FRSYNC_8K_1PPS and MFRSYNC_2K_1PPS frequencies are selected through the DPLL1_fr_mfr_sync_cfg registers.

Any supported clock frequency at the clock input can be associated with the sync signals.

The frame sync output signals are derived from the DPLL1 and DPLL2 output and are aligned with the output clock. They are synchronized to the frame sync input signal. In DCO control modes (section 3.2.2.1.6), the output FRSYNC_8K_1PPS and MFRSYNC_2K_1PPS signals must not be used, a 1PPS output sync signal can be generated in any of the output clocks connected to the DCO being used.

The frame sync output signals are derived from the DPLL1 output and are aligned with the output clock. They are synchronized to the frame sync input signal.

The frame/sync output signals align to the first edge of the associated reference clock that occurs after the edge of the frame/sync input signal. The frequency of the associated reference clock must be lower or equal to the frequencies of the output clocks that requires to be aligned with the frame/sync pulse signal.

If the frame sync input signal with respect to the DPLL1 selected input clock is above a limit set by the SYNC_MON_LIMT[2:0] bits, an external sync alarm will be raised and the frame/sync input signal is disabled to synchronize the frame/sync output signals. The external sync alarm is cleared once the frame/sync input signal with respect to the
DPLL selected input clock is within the limit. If it is within the limit, whether frame/sync input signal is enabled to synchronize the frame sync output signal is determined by the AUTO_EXT_SYNC_EN bit and the EXT_SYNC_EN bit.

When the frame/sync input signal is enabled to synchronize the frame/sync output signal, it is adjusted to align itself with the DPLL selected input clock.

By default, the falling edge of the frame/sync input signal is aligned with the rising edge of the DPLL1 selected input clock. The rising edge of frame/sync input signal can be set to be aligned with the rising edge of the DPLL1 selected input clock by setting sync_edge bit to “1” in DPLL1_sync_edge_cfg register.

The EX_SYNC_ALARM_MON bit indicates whether frame/sync input signal is in external sync alarm status. The external sync alarm is indicated by the EX_SYNC_ALARM bit. If the EX_SYNC_ALARM bit is ‘1’, the occurrence of the external sync alarm will trigger an interrupt.

The 8 kHz frame pulse, the 2 kHz frame pulse, and the 1PPS sync signal can be inverted by setting the 8K_1PPS_INV and 2K_1PPS_INV bits of Frame Sync and Multiframe Sync Output Configuration Register.

The 8 kHz and the 2 kHz frame sync outputs can be 50:50 duty cycle or pulsed, as determined by the 8K_PUL and 2K_PUL bits respectively. When they are pulsed, the pulse width derived from DPLL1 is defined by the period of OUT1. They are pulsed on the position of the falling or rising edge of the standard 50:50 duty cycle, as selected by the 2K_8K_PUL_POSITION bit of Frame Sync and Multiframe Sync Output Configuration Register.

3.2.7 INPUT AND OUTPUT PHASE CONTROL

The device has several features to allow a tight control of the phase on the input and output clocks.

3.2.7.1 DPLL1 Phase offset control

The phase offset of the DPLL1 selected input clock with respect to the DPLL1 output can be adjusted. If the device is configured as the active PLL in a redundancy system, then the PH_OFFSET_EN bit determines whether the input-to-output phase offset is enabled. If the device is configured as the inactive PLL in a redundancy system, then the input-to-output phase offset is always enabled. If enabled, the input-to-output phase offset can be adjusted by setting the PH_OFFSET_CNFG[28:0] bits in DPLL1 phase offset configuration register. The register value is a 2’s complement phase offset with a resolution of 0.0745ps and a total range of [20us, -20us].

The input-to-output phase offset can be calculated as follows:

\[
\text{Phase Offset (ps)} = \text{PH_OFFSET}[28:0] \times 0.0745
\]
3.2.7.2 Input Phase control

All the inputs phase can be controlled individually. They can be programmed with a resolution of 0.61 ns and a range of [77.5 ns, -78.1 ns] by setting INn_PHASE_OFFSET_CNFG[7:0] bits (1 ≤ n ≤ 6) in the input phase offset configuration register. The register value is a 2's complement phase offset, the default is zero. The programmed offset is automatically applied to the DPLL1 when a particular input is selected. If the manual DPLL1 phase offset control is used then the per-input phase offset is not applied.

3.2.7.3 Output Phase control

The output phase can be controlled individually for outputs OUT1 to OUT8. There is the coarse phase control that allows the output phase to be adjusted as low as 1.6 ns. There is a fine phase adjustment that allows the output phase to be adjusted as low as 187.27 ps. The total range is +/-180°.

There are two registers associated with the coarse phase adjustment, the OUTn_PH1_CNFG (1 ≤ n ≤ 8) and the OUTn_PH2_CNFG (1 ≤ n ≤ 8) registers. The OUTn_PH1_CNFG register is associated with output divider 1 as shown in Figure 13 and Figure 14, the phase can be adjusted by a step size that is equal to the period of the input of clock of the output Div1, the number set in the OUTn_PH1_CNFG register should not be larger than the number set in OUTn_DIV1_CNFG register. The OUTn_PH2_CNFG register is associated with output divider 2 as shown in Figure 13 and Figure 14, the phase can be adjusted by a step size that is equal to the period of the input of clock of the output Div2, the number set in the OUTn_PH2_CNFG register should not be larger than the number set in OUTn_DIV2_CNFG register.

There is a register that is associated with the fine phase adjustment, the OUTn_FINE_CNFG (1 ≤ n ≤ 8). For the fine phase adjustment, the output clocks must be output from the APLLs. The phase can be adjusted by a step size that is equal to the 1/2 of the period of the VCO. For Ethernet clocks the VCO frequency is 2.5 GHz, for Ethernet LAN PHY the VCO frequency is 2.578125 GHz, and for SONET/SDH clocks the VCO frequency is 2.48832 GHz. OUT1 can be output from the DPLLs, and in that case the fine phase adjustment is not available, it is only available if the clocks are output from the APLLs.

The output phase adjustments are not available for OUT9 and OUT10.
4 POWER SUPPLY FILTERING TECHNIQUES

To achieve optimum jitter performance, power supply filtering is required to minimize supply noise modulation of the output clocks. The common sources of power supply noise are switch power supplies and the high switching noise from the outputs to the internal PLL. The 82P33714 provides separate VDDA and VDDAO power pins for the internal analog PLL, it also provides VDDD and VDDDO pins for the core logic as well as I/O driver circuits.

The suggested power decoupling scheme is shown in Figure 15.
Figure 15. 82P33714 Power Decoupling Scheme
5 MICROPROCESSOR INTERFACE

The microprocessor interface provides access to read and write the registers in the device. The microprocessor interface supports I2C.

5.1 I2C SLAVE MODE

5.1.1 I2C DEVICE ADDRESS

The default value for the higher 4-bit address is 4'b1010, the 3-bit address is set by pins I2C_AD2, I2C_AD1, and I2C_AD0.

5.1.2 I2C BUS TIMING

Figure 16 shows the definition of I2C bus timing.

</tbody>
</table>

Note:
1. All values referred to V\(_{IH\text{min}}\) and V\(_{IL\text{max}}\) levels (see Table 23)
2. A device must Internally provide a hold time of at least 300 ns for the SDA signal (referred to the V\(_{IH\text{min}}\) of the SCL signal) to bridge the undefined region of the falling edge of SCL.
3. The maximum t\(_{HD; DAT}\) is only to be met if the device does not stretch the LOW period (t\(_{LOW}\)) of the SCL signal.
4. A Fast-mode I\(_2\)C-bus device can be used in a Standard-mode I\(_2\)C-bus system, but the requirement t\(_{SU; DAT}\) ≥ 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line t\(_{max}\) + t\(_{SU; DAT}\) = 1000 + 250 = 1250 ns (according to the Standard-mode I\(_2\)C-bus specification) before the SCL line is released.
5. C\(_{p}\) = total capacitance of one bus line in pF. If mixed with Hs-mode device, faster fall-times according to Table 24 allowed.

</tr>
</tbody>
</table>

The registers are divided up into pages of 128 bytes with each byte having a separate address. Multi-byte registers need to be accessed in multiple read/write cycles. Address 0x7F is reserved for the page index pointer.

All register accesses are done as 8 bit I2C cycles. The 8-bit address refers to the register offset within the active page. If access to a different page is needed then a separate I2C write must be performed to the page register (0x7F). This makes the new page active and then 8 bit reads and writes can be performed anywhere within that page.

Note that accesses to multi-byte registers should not be interrupted by accesses to other addresses, because that may cause the data to be corrupted. The access of the multi-byte registers is different from that of the single-byte registers. Take the DPLL1 priority table registers (00H and 01H in page 2) as an example, the write operation for the multi-byte registers follows a fixed sequence. The register (00H) is configured first and the register (01H) is configured last. The two registers are configured continuously and should not be interrupted by any operation. The DPLL1 priority table configuration will take effect after all the two registers are configured. During read operation, the register (00H) is read first and the register (01H) is read last. The priority table configuration register reading should be continuous and not be interrupted by any operation.

5.2 I2C MASTER MODE

The 82P33714 has the capability to read from an external I2C EEPROM upon exit from reset. This reduces the start-up load on the microprocessor by programming the registers in the device-address space 101_0xxx. This mode uses the MPU_MODE1/I2CM_SCL and the MPU_MODE0/I2CM_SDA pins as the serial clock and the serial data respectively, it requires that both these pins be pulled high through resistors (these resistor values are dependent on the bus capacitance and I2C speed of the application). Access to the 82P33714 registers through the microprocessor interface I2C serial port is not available until the EEPROM reading process is completed.

As an I2C bus master, the 82P33714 will support the following:

- 8 kbit (1023 x 8) I2C EEPROM with device address 1010000 (for the base block)
- Sequential read (block read) of the entire memory-map for device, from byte-address 0x000 to 0x39E
- 7-bit device address mode
- Validation of the EEPROM read data via CCITT-8 CRC check against value stored in memory-map address 0x39E
- Support for 100 kHz and 400 kHz operation with speed programmability. If bit 7 is set at memory-map address 0x001, the 82P33714 will shift from 100 kHz operation to 400 kHz operation.
- 2-byte word-addressing (1-byte word addressing is supported by offsetting the memory-map upwards 1 address in the EEPROM)
- Read will abort with an alarm (RD_EEPROM_ERR interrupt status set) if any of the following conditions occur: Slave NACK, CRC failure, Slave Response time-out
As the 82P33714 I2C master bus is meant only to read from a single EEPROM, it has the following restrictions:

- No support for Multi-master
- No support for Slave clock stretching
- No support for I2C Start Byte protocol
- No support for EEPROM Chaining
- No support for Writing to external I2C devices including the EEPROM used for booting

5.2.1 I2C BOOT-UP INITIALIZATION MODE

EEPROM mode is enabled via setting the MPU_MODE[1:0] pins high (through two separate pull-up resistors). Once the RSTB input has been asserted (low) and then de-asserted (high) and the device internal calibration has been completed, the 82P33714 will perform a short block read at 100 kHz to program the EEPROM read speed (100 kHz or 400 kHz). The 82P33714 will then perform a block read to program all the device configuration registers, and check the CRC of the EEPROM data. During the boot-up EEPROM-reading process, the 82P33714 will not respond to microprocessor serial control port accesses. Once the initialization process is completed, the contents of any of the device configuration registers can be further altered by the microprocessor, if desired.

The 82P33714 can work with EEPROMs supporting 2-byte word-addresses or 1-byte word-addresses by using 2-byte word addressing for both. This works in the usual manner for EEPROMs supporting 2-byte word addresses, and gives an address-to-address match between EEPROM and memory-map. For EEPROMs supporting only 1-byte word addresses, the second address byte will cause an addition increment of the address counter, and the memory-map will be read at the next highest EEPROM address, i.e. memory-map address 0x00 will be read from EEPROM address 0x01, and memory-map address 0x39E will be read from EEPROM address 0x39F.

If a NACK is received to any of the read cycles performed by the 82P33714 during the initialization process, or if the CRC does not match the one stored in memory-map address 0x39E, the boot process will be restarted. This restart can happen up to three times before an abort is declared and the RD_EEPROM_ERR interrupt status bit is set. Also on RD_EEPROM_ERR the MPU_MODE1/I2CM_SCL and MPU_MODE0/I2CM_SDA pins are both held low until the interrupt status bit is cleared or the device is reset. The suggested method for dealing with RD_EEPROM_ERR is to externally set the MPU_MODE[1:0] pins to 00 and then reset the 82P33714 so that it will boot into I2C serial port mode.

After a successful EEPROM boot, the 82P33714 will stop toggling the MPU_MODE1/I2CM_SCL and MPU_MODE0/I2CM_SDA pins, returning them to static high values, and the RD_EEPROM_DONE interrupt status bit will be set. The I2C serial port will now respond to microprocessor reads and writes to the appropriate I2C device address.

5.2.2 EEPROM MEMORY MAP NOTES

The EEPROM memory-map is the same as the control and status register (CSR) map with the following additions and constraints:

1. For EEPROMs supporting 2-byte word-address, the memory-map addresses are the same as the EEPROM addresses; for EEPROMs supporting 1-byte word-address, the memory-map addresses will be mapped to the next address in the EEPROM, i.e. memory-map address 0x00 will be read from EEPROM address 0x01, and memory-map address 0x39E will be read from EEPROM address 0x39F.

2. Memory-map address 0x001, bit 7 is the EEPROM read speed (0 for 100 kbps, 1 for 400 kbps)

3. Memory-map address 0x39E is the CRC-8 of the memory-map from 0x000 to 0x39D (the standard CCITT CRC-8 with the data width and result width being 8; the polynomial is (0, 1, 2, 8) or “0x07”). NB: all memory-map addresses from 0x000 to 0x39d are included in the sequential calculation of CRC, including those not used in the CSR - it is recommend that data at unused addresses be set to 0x00.

4. Memory-map addresses 0x392 to 0x39D must be set to the default values shown in the CSR documentation.

5. The device address at memory-map address 0x00f must match the address set by the board.

6. Each memory-map address that is a multiple of 0x7F must contain the pointer to the next page of the CSR i.e

5.3 SERIAL MODE

In a read operation, the active edge of SCLK is selected by CLKE. When CLKE is asserted low, data on SDO will be clocked out on the rising edge of SCLK. When CLKE is asserted high, data on SDO will be clocked out on the falling edge of SCLK.

In a write operation, data on SDI will be clocked in on the rising edge of SCLK.

5.4 UART MODE

When the 82P33714 comes out of reset with the MPU_MODE[1:0] pins set to ‘b10, or when the boot-up EEPROM sets the mpu_sel_cfg[1:0] bits to ‘b10, the device will set its serial port mode to support simple 2-pin UART (Universal Asynchronous Receiver/Transmitter) communications. The UART_RX pin is used as the receive data, (data into the device), and the UART_TX pin is used as the transmit data, (data out of the device). The supported byte-protocol is 1 Start bit, 8 data bits, and 1 Stop bits, with no parity. Figure 21 shows the UART data frame.

![Figure 21. UART Data Frame](image)

The falling edge of the Start bit is used to synchronize the UART receiver with the transmitter of the micro-controller; each bit is sampled at the expected midpoint as determined by this falling edge and the programmed baud rate.

The baud rate is programmed using the two control registers: baud_rate_cfg, and baud_limit_cfg. These registers set up an M/N divider from the 82P33714 system clock rate (77.76 MHz) down to the desired sample-clock rate, which must be 16 times the desired baud rate. The baud_freq_cfg register is programmed with the M value, and the baud_limit_cfg register is programmed with the value (N - M). These registers may be programmed by the boot-up EEPROM, or over the serial UART link. The new values take effect as soon as the UART goes idle, so it is recommended that all 4 bytes be written in one burst.

Example Baud rates:

**9600 baud (default)**
- Sample Clock Rate = 16 * 9600 = 153 600 Hz
- Sample Clock Rate = 77.76 MHz * 4/2025 = 153 600 Hz
- baud_freq_cfg = 4 = x004
- baud_limit_cfg = 2025 - 4 = 2021 = x07E5

**115 200 baud**
- Sample Clock Rate = 16 * 115 200 = 1 843 200 Hz
- Sample Clock Rate = 77.76 MHz * 16/675 = 1 843 200 Hz
- baud_freq_cfg = 16 = x10
- baud_limit_cfg = 675 - 16 = 659 = x293

Reads and writes of the 82P33714 control and status registers are performed through a multi-frame/byte binary protocol, which is more efficient than a character-oriented (hyper-terminal) protocol. The UART will auto-increment the internal address to support burst reads and writes for even higher efficiency.

5.4.1 PROTOCOL

Reads and writes are initiated by the micro-controller sending a command to the 82P33714. All commands start with a zero byte, followed by a command byte, 2 address bytes, and a length byte, which specifies the number of bytes to be written or read. Write commands then have a number of data bytes as given by the length byte. Commands are optionally acknowledged on completion.

| Byte 1     | Zero byte                  |
| Byte 2     | Command byte               |
| Byte 3     | High Address byte (always zero) |
| Byte 4     | Low Address byte           |
| Byte 5     | Length byte                |
| Byte 6 to 5+Length | Write data bytes (if a write command) |

The format of the command byte is given in Table 16.

<table>

</tr>
<tr>
<td>1</td>
<td>Send ACK Flag:</td>
</tr>
<tr>
<td></td>
<td>Set to 1 to send ACK byte at command completion.</td>
</tr>
</tbody>
</table>

Note that bursts cannot exceed the boundary of one register page (128 bytes), also the Address + Length should not reach the page register at the top of the register page (address 127 / x3F).

When the micro-controller sends a read command, or requests an acknowledge byte, the 82P33714 will transmit one of more bytes as follows:

- Byte 1 to Length | Read Data bytes |
- Byte 'Length 'ACK byte (0x5A, if bit[0] of the Command byte was set]

Although the UART command contains a two-byte address, the 82P33714 will only use the Low Address byte. The UART can be set to expect a single byte address by clearing the uart_double_address bit in the baud_freq_cfg[11:8] register. The command protocol can then leave out the High Address byte.
6 JTAG

This device is compliant with the IEEE 1149.1 Boundary Scan standard except the following:

- The output boundary scan cells do not capture data from the core and the device does not support EXTEST instruction;

The JTAG interface timing diagram is shown in Figure - 22.

7 THERMAL MANAGEMENT

The device operates over the industry temperature range -40°C ~ +85°C. To ensure the functionality and reliability of the device, the maximum junction temperature $T_{j\text{max}}$ should not exceed 125°C. In some applications, the device will consume more power and a thermal solution should be provided to ensure the junction temperature $T_j$ does not exceed the $T_{j\text{max}}$.

7.1 JUNCTION TEMPERATURE

Junction temperature $T_j$ is the temperature of package typically at the geographical center of the chip where the device's electrical circuits are. It can be calculated as follows:

$$T_j = T_A + P \times \theta_{JA}$$

Where:

- $\theta_{JA}$ = Junction-to-Ambient Thermal Resistance of the Package
- $T_j$ = Junction Temperature
- $T_A$ = Ambient Temperature
- $P$ = Device Power Consumption

In order to calculate junction temperature, an appropriate $\theta_{JA}$ must be used. The $\theta_{JA}$ is shown in Table 18:

Table 18 has the thermal results based on JEDEC standard conditions. It is industry practice and IDT practice to publish these results.

If the PCB design differs from the JEDEC standard conditions, then the thermal results will be different.

7.2 THERMAL RELEASE PATH

In order to maximize both the removal of heat from the package, electrical grounding from the package to the board can be done through thermal vias to effectively conduct from the surface of the PCB to the ground plane(s). The vias act as “heat pipes”. The number of vias (i.e. “heat pipes”) are application specific and dependent upon the package power dissipation as well as electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13mils (0.30 to 0.33mm) with 1oz copper via barrel plating. These recommendations are to be used as a guideline only.

8.3.2.2   LVPECL Output Port

8.3.2.2.1   LVPECL Termination for 3.3 V

The clock layout topology shown below is a typical termination for LVPECL outputs. The two different layouts mentioned are recommended only as guidelines.

The differential outputs are low impedance follower outputs that generate ECL/LVPECL compatible outputs. Therefore, terminating resistors (DC current path to ground) or current sources must be used for functionality. These outputs are designed to drive 50\(\Omega\) transmission lines. Matched impedance techniques should be used to maximize operating frequency and minimize signal distortion. Figure 24 and Figure 25 show two different layouts which are recommended only as guidelines. Other suitable clock layouts may exist and it would be recommended that the board designers simulate to guarantee compatibility across all printed circuit and clock component process variations.

**Figure 24. 3.3V LVPECL Output Termination**

**Figure 25. 3.3V LVPECL Output Termination**
8.3.2.2.2 LVPECL Termination for 2.5 V

Figure 26 and Figure 27 show examples of termination for 2.5V LVPECL driver. These terminations are equivalent to terminating 50Ω to VCCO – 2V. For VCCO = 2.5V, the VCCO – 2V is very close to ground level. The R3 in Figure 27 can be eliminated and the termination is shown in Figure 28.

8.3.3.2 LVDS Output Port

LVDS Driver Termination

For a general LVDS interface, the recommended value for the termination impedance ($Z_T$) is between $90\,\Omega$ and $132\,\Omega$. The actual value should be selected to match the differential impedance ($Z_0$) of your transmission line. A typical point-to-point LVDS design uses a $100\,\Omega$ parallel resistor at the receiver and a $100\,\Omega$ differential transmission-line environment. In order to avoid any transmission-line reflection issues, the components should be surface mounted and must be placed as close to the receiver as possible. IDT offers a full line of LVDS compliant devices with two types of output structures: current source and voltage source. The standard termination schematic as shown at the top part of Figure 30 can be used with either type of output structure. The termination schematic shown at the bottom part of Figure 30, which can also be used with both output types, is an optional termination with center tap capacitance to help filter common mode noise. The capacitance value should be approximately $50\,\text{pF}$. If using a non-standard termination, it is recommended to contact IDT and confirm if the output structure is current source or voltage source type. In addition, since these outputs are LVDS compatible, the input receiver's amplitude and common-mode input range should be verified for compatibility with the output.

8.3.4.1 Single-Ended Input for Differential Input

Figure 32 shows how a differential input can be wired to accept single ended levels. The reference voltage V<sub>REF</sub> = V<sub>CC</sub>/2 is generated by the bias resistors R<sub>1</sub> and R<sub>2</sub>. The bypass capacitor (C<sub>1</sub>) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of R<sub>1</sub> and R<sub>2</sub> might need to be adjusted to position the V<sub>REF</sub> in the center of the input voltage swing. For example, if the input clock swing is 2.5V and V<sub>CC</sub> = 3.3V, R<sub>1</sub> and R<sub>2</sub> value should be adjusted to set V<sub>REF</sub> at 1.25V. The values below are for when both the single ended swing and V<sub>CC</sub> are at the same voltage. This configuration requires that the sum of the output impedance of the driver (R<sub>o</sub>) and the series resistance (R<sub>s</sub>) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways.

First, R<sub>3</sub> and R<sub>4</sub> in parallel should equal the transmission line impedance. For most 50Ω applications, R<sub>3</sub> and R<sub>4</sub> can be 100Ω. The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver. When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVCMOS signaling, it is recommended that the amplitude be reduced. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however V<sub>IL</sub> cannot be less than -0.3V and V<sub>IH</sub> cannot be more than V<sub>CC</sub> + 0.3V. Suggest edge rate faster than 1V/μs. Though some of the recommended components might not be used, the pads should be placed in the layout. They can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

![Figure 32. Example of Single-Ended Signal to Drive Differential Input](image)

V<sub>th</sub> = V<sub>CC</sub>*[R<sub>2</sub>/(R<sub>1</sub>+R<sub>2</sub>)]

For the example in Figure 32, R<sub>1</sub> = R<sub>2</sub>, so V<sub>th</sub> = V<sub>CC</sub>/2 = 1.65 V

The suggested single-ended signal input:

V<sub>ILmax</sub> = V<sub>CC</sub>
V<sub>ILmin</sub> = 0 V

V<sub>swing</sub> = 0.6 V = V<sub>CC</sub>
DC offset (Swing Center) = V<sub>th</sub>/2 +/- V<sub>swing</sub>*10%
## 8.4 JITTER PERFORMANCE

8.5 INPUT / OUTPUT CLOCK TIMING

The inputs and outputs are aligned ideally. But due to the circuit delays, there is delay between the inputs and outputs.

![Figure 33. Input / output clock timing](image)

Table 36: Input-to-Output Delay via APLL1/2

<table>
<thead>
<tr>
<th>Output</th>
<th>(t_1) Min (ns)</th>

</tr>
</tbody>
</table>

NOTE 1. The measurements in the above table takes into account any delays in the clock path from any input to any output; through DPLL2 and either APLL1 or APLL2.

NOTE 2. The measurements in the above table are over operational temperature, varying power supply and repeated power on/off cycle.

NOTE 3. Measurements are taken using an ideal REF input and an ideal System clock to account for only internal delays in the device.

“G” after the two-letter package code denotes Pb-Free configuration, RoHS compliant.
## REVISION HISTORY

<table>
<thead>
<tr>
<th>Revision Date</th>
<th>Description of Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>August 21, 2018</td>
<td>Added Figure 31</td>
</tr>
<tr>
<td>June 15, 2018</td>
<td>• Updated the <a href="https://www.idt.com/go/support">Package Outline Drawings</a> to append to the datasheet upon download from IDT.com; no mechanical changes.</td>
</tr>
<tr>
<td></td>
<td>• Revision history note: The April 20, 2015 release of the 82P33714 Datasheet contained a change to Input Clock Loss of Signal that was not included in the document’s revision history. This was a documentation change only – there was no change to the form, fit, or function of the 82P33714. The text was changed as follows:</td>
</tr>
<tr>
<td></td>
<td>From:</td>
</tr>
<tr>
<td></td>
<td>There are 4 LOS input pins (LOS[3:0]) that can be used to disqualify the input clock. If they are set to zero, then the associated input clock is disqualified to be used as an input clock, and therefore the DPLLs will not lock to that particular input clock.</td>
</tr>
<tr>
<td></td>
<td>To:</td>
</tr>
<tr>
<td></td>
<td>There are 4 LOS input pins (LOS[3:0]) that can be used to disqualify the input clock. If they are set high, then the associated input clock is disqualified to be used as an input clock, and therefore the DPLLs will not lock to that particular input clock.</td>
</tr>
<tr>
<td>August 25, 2017</td>
<td>Added MS/SL PIN USAGE</td>
</tr>
<tr>
<td></td>
<td>Updated Table 8</td>
</tr>
<tr>
<td>July 19, 2017</td>
<td>Updated the description of MS/SL in Table 1</td>
</tr>
<tr>
<td></td>
<td>Updated the Package Outline Drawings; however, no mechanical changes.</td>
</tr>
<tr>
<td>January 23, 2017</td>
<td>Pages 3-4, 60</td>
</tr>
<tr>
<td>January 9, 2017</td>
<td>Pages, 1, 4, 22, 23, 28-29, 60</td>
</tr>
<tr>
<td>March 28, 2016</td>
<td>Page 31, 52</td>
</tr>
<tr>
<td>June 10, 2015</td>

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.

2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.

3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.

5. Renesas Electronics products are classified according to the following two quality grades. "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

   "Standard":
   - Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

   "High Quality":
   - Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user’s manual or other Renesas Electronics document.

6. When using Renesas Electronics products, refer to the latest product information (data sheets, user’s manuals, application notes, “General Notes for Handling and Using Semiconductor Devices” in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.

7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of micromodule computer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.

8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.

10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.

11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.
