FEATURES

- Single channel T1/E1/J1 long haul/short haul line interface
- Supports HPS (hitless protection Switching) for 1+1 protection without external relays
- Receiver sensitivity exceeds -36 dB@772KHz and -43 dB@1024 KHz
- Programmable T1/E1/J1 switchability allowing one bill of material for any line condition
- Single 3.3 V power supply with 5 V tolerance on digital interfaces
- Meets or exceeds specifications in
  - ANSI T1.102, T1.403 and T1.408
  - ITU I.431, G.703, G.736, G.775 and G.823
  - ETSI 300-166, 300-233 and TBR12/13
  - AT&T Pub 62411
- Software programmable or hardware selectable on:
  - Wave-shaping templates for short haul and long haul LBO (Line Build Out)
  - Line terminating impedance (T1:100 Ω, J1:110 Ω, E1:75 Ω/120 Ω)
  - Adjustment of arbitrary pulse shape
  - JA (Jitter Attenuator) position (receive path or transmit path)
  - Single rail/dual rail system interfaces
  - B8ZS/HDB3/AMI line encoding/decoding
  - Active edge of transmit clock (TCLK) and receive clock (RCLK)
  - Active level of transmit data (TDATA) and receive data (RDATA)
- Receiver or transmitter power down
- High impedance setting for line drivers
- PRBS (pseudo random bit sequence) generation and detection with 2^{15}-1 PRBS polynomials for E1
- QRSS (quasi random signal source) generation and detection with 2^{20}-1 QRSS polynomials for T1/J1
- 16-bit BPV (bipolar pulse violation) /excess zero/PRBS or QRSS error counter
- Analog loopback, digital loopback, remote loopback and inband loopback
- Cable attenuation indication
- Adaptive receive sensitivity
- Short circuit protection and internal protection diode for line drivers
- AIS (alarm indication signal) detection
- Supports serial control interface, Motorola and Intel multiplexed interfaces and hardware control mode
- Pin compatible 82V2041E T1/E1/J1 short haul LIU and 82V2051E E1 short haul LIU
- Package:
  - Available in 44-pin TQFP and 48-pin QFN packages

DESCRIPTION

The IDT82V2081 can be configured as a single channel T1, E1 or J1 line interface unit. In the receive path, an adaptive equalizer is integrated to remove the distortion introduced by cable attenuation. The IDT82V2081 also performs clock/data recovery, AMI/B8ZS/HDB3 line decoding and detects and reports LOS conditions. In the transmit path, there is an AMI/ B8ZS/HDB3 encoder, waveform shaper and LBOs. There is one jitter attenuator, which can be placed in either the receive path or the transmit path. The jitter attenuator can also be disabled. The IDT82V2081 supports both single rail and dual rail system interfaces. To facilitate the network maintenance, a PRBS/QRSS generation/detection circuit is integrated in the chip, and different types of loopbacks can be set according to the applications. Four different kinds of line terminating impedance, 75 Ω, 100 Ω, 110 Ω and 120 Ω are selectable. The IDT82V2081 also provides driver short-circuit protection and internal protection diodes. The IDT82V2081 can be controlled by either software or hardware.

The IDT82V2081 can be used in LAN, WAN, routers, wireless base stations, IADs, IMAs, IMAPs, gateways, frame relay access devices, CSU/DSU equipment, etc.

<td>Data on RDP/RDN or RD is clocked with either the rising or the falling edge of RCLK. The active polarity is also selectable.</td>
</tr>
</tbody>
</table>

**Notes:**

1. TCLK missing: the state of TCLK continues to be high level or low level over 70 MCLK cycles.
### RCLK: Receive Clock output
This pin outputs 1.544 MHz for T1/J1 mode or 2.048 MHz for E1 mode receive clock. Under LOS condition with AIS enabled (bit AISE=1), RCLK is derived from MCLK. In clock recovery mode, this signal provides the clock recovered from the RTIP/RRING signal. The receive data (RD in single rail mode or RDP and RDN in dual rail mode) is clocked out of the device on the active edge of RCLK. If clock recovery is bypassed, RCLK is the exclusive OR (XOR) output of the dual rail slicer data RDP and RDN. This signal can be used in applications with external clock recovery circuitry.

### MCLK: Master Clock input
A built-in clock system that accepts selectable 2.048MHz reference for E1 operating mode and 1.544MHz reference for T1/J1 operating mode. This reference clock is used to generate several internal reference signals:
- Timing reference for the integrated clock recovery unit.
- Timing reference for the integrated digital jitter attenuator.
- Timing reference for microcontroller interface.
- Generation of RCLK signal during a loss of signal condition.
- Reference clock to transmit All Ones, all zeros, PRBS/QRSS pattern as well as activate or deactivate Inband Loopback code if MCLK is selected as the reference clock. Note that for ATAO and AIS, MCLK is always used as the reference clock.
- Reference clock during the Transmit All Ones (TAO) condition or sending PRBS/QRSS in hardware control mode. The loss of MCLK will turn TTIP/TRING into high impedance status.

### LOS: Loss of Signal Output
This is an active high signal used to indicate the loss of received signal. When LOS pin becomes high, it indicates the loss of received signal. The LOS pin will become low automatically when valid received signal is detected again. The criteria of loss of signal are described in 3.6 Los And AIS Detection.

### REF: reference resister
An external resistor (3 KΩ, 1%) is used to connect this pin to ground to provide a standard reference current for internal circuit.

### MODE[1:0]: operation mode of Control interface select
The level on this pin determines which control mode is used to control the device as follows:

<table>
<thead>
<tr>
<th>MODE[1:0]</th>
<th>Control Interface mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Hardware interface</td>
</tr>
<tr>
<td>01</td>
<td>Serial Microcontroller Interface</td>
</tr>
<tr>
<td>10</td>
<td>Parallel –Multiplexed -Motorola Interface</td>
</tr>
<tr>
<td>11</td>
<td>Parallel –Multiplexed -Intel Interface</td>
</tr>
</tbody>
</table>

- The serial microcontroller Interface consists of CS, SCLK, SCLKE, SDI, SDO and INT pins. SCLKE is used for the selection of the active edge of SCLK.
- The parallel multiplexed microcontroller interface consists of CS, AD[7:0], DS/RD, R/W/WR, ALE/AS, ACK/RDY and INT pins. (refer to 3.12 Microcontroller Interfaces for details)
- Hardware interface consists of PULS[3:0], THZ, RCLKE, LP[1:0], PATT[1:0], JA[1:0], MONT, TERM, EQ, RPD, MODE[1:0] and RXTXM[1:0]

### RCLKE: the active edge of RCLK select
In hardware control mode, this pin selects the active edge of RCLK:
- L= select the rising edge as the active edge of RCLK
- H= select the falling edge as the active edge of RCLK

In software control mode, this pin should be connected to GNDIO.

|       |      |                 |                | This signal enables or disables transmitter driver. A low level on this pin enables the driver while a high level on this pin places driver in high impedance state. Note that the functionality of the internal circuits is not affected by this signal. |

Power Supplies and Grounds

- **VDDIO** - 3.3 V I/O power supply  
- **GNDIO** - I/O ground  
- **VDDT** - 3.3 V power supply for transmitter driver  
- **GNDT** - Analog ground for transmitter driver  
- **VDDA** - 3.3 V analog core power supply  
- **GNDA** - Analog core ground  
- **VDDD** - Digital core power supply  
- **GNDD** - Digital core ground

Others

- **IC1** - Internal connection  
  Internal Use. This pin should be left open when in normal operation.  
- **IC2** - Internal connection  
  Internal Use. This pin should be connected to ground when in normal operation.  
- **nc** - Not connected  
  These pins should be left open.
3 FUNCTIONAL DESCRIPTION

3.1 CONTROL MODE SELECTION

The IDT82V2081 can be configured by software or by hardware. The software control mode supports Serial Control Interface, Motorola Multiplexed Control Interface and Intel Multiplexed Control Interface. The control mode is selected by MODE1 and MODE0 pins as follows:

<table>
<thead>
<tr>
<th>Control Interface mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Hardware interface</td>
</tr>
<tr>
<td>01</td>
<td>Serial Microcontroller Interface.</td>
</tr>
<tr>
<td>10</td>
<td>Parallel –Multiplexed -Motorola Interface</td>
</tr>
<tr>
<td>11</td>
<td>Parallel –Multiplexed -Intel Interface</td>
</tr>
</tbody>
</table>

- The serial microcontroller Interface consists of CS, SCLK, SCLKE, SDI, SDO and INT pins. SCLKE is used for the selection of active edge of SCLK.
- The parallel Multiplexed microcontroller Interface consists of CS, AD[7:0], DS/DR, RI/RW, ALE/AS, ACK/RDY and INT pins.
- Hardware interface consists of PULS[3:0], THZ, RCLKE, LP[1:0], PATT[1:0], JA[1:0], MONT, TERM, EQ, RPD, MODE[1:0] and RXTXM[1:0]. Refer to chapter 5 Hardware Control Pin Summary for details about hardware control.

3.2 T1/E1/J1 MODE SELECTION

When the chip is configured by software, T1/E1/J1 mode is selected by the T1E1 bit (GCF, 02H). In E1 application, the T1E1 bit (GCF, 02H) should be set to ‘0’. In T1/J1 application, the T1E1 bit should be set to ‘1’.

When the chip is configured by hardware, T1/E1/J1 mode is selected by PULS[3:0] pins. These pins also determine transmit pulse template and internal termination impedance. Refer to 5 Hardware Control Pin Summary for details.

3.3 TRANSMIT PATH

The transmit path of IDT82V2081 consists of an Encoder, an optional Jitter Attenuator, a Waveform Shaper, a set of LBOs, a Line Driver and a Programmable Transmit Termination.

3.3.1 TRANSMIT PATH SYSTEM INTERFACE

The transmit path system interface consists of TCLK pin, TD/TDP pin and TDN pin. In E1 mode, TCLK is a 2.048 MHz clock. In T1/J1 mode, TCLK is a 1.544 MHz clock. If TCLK is missing for more than 70 MCLK cycles, an interrupt will be generated if it is not masked.

Transmit data is sampled on the TD/TDP and TDN pins by the active edge of TCLK. The active edge of TCLK can be selected by the TCLK_SEL bit (TCF0, 05H). And the active level of the data on TD/TDP and TDN can be selected by the TD_INV bit (TCF0, 05H). In hardware control mode, the falling edge of TCLK and the active high of transmit data are always used.

The transmit data from the system side can be provided in two different ways: Single Rail and Dual Rail. In Single Rail mode, only TD pin is used for transmitting data and the T_MD[1] bit (TCF0, 05H) should be set to ‘0’. In Dual Rail mode, both TDP and TDN pin are used for transmitting data, the T_MD[1] bit (TCF0, 05H) should be set to ‘1’.

3.3.2 ENCODER

In Single Rail mode, when T1/J1 mode is selected, the Encoder can be configured to be a B8ZS encoder or an AMI encoder by setting T_MD[0] bit (TCF0, 05H).

In Single Rail mode, when E1 mode is selected, the Encoder can be configured to be an HDB3 encoder or an AMI encoder by setting T_MD[0] bit (TCF0, 05H).

In both T1/J1 mode and E1 mode, when Dual Rail mode is selected (bit T_MD[1] is ‘1’), the Encoder is by-passed. In Dual Rail mode, a logic ‘1’ on the TDP pin and a logic ‘0’ on the TDN pin results in a negative pulse on the TTIP/TRING. A logic ‘0’ on TDP pin and a logic ‘1’ on TDN pin results in a positive pulse on the TTIP/TRING. If both TDP and TDN are high or low, the TTIP/TRING outputs a space (Refer to TD/TDP, TDN Pin Description).

In hardware control mode, the operation mode of receive and transmit path can be selected by setting RXTXM1 and RXTXM0 pins. Refer to 5 Hardware Control Pin Summary for details.

3.3.3 PULSE SHAPER

The IDT82V2081 provides three ways of manipulating the pulse shape before sending it. The first is to use preset pulse templates for short haul application, the second is to use LBO (Line Build Out) for long haul application and the other way is to use user-programmable arbitrary waveform template.

In software control mode, the pulse shape can be selected by setting the related registers.

In hardware control mode, the pulse shape can be selected by setting PULS[3:0] pins. Refer to 5 Hardware Control Pin Summary for details.

3.3.3.1 PRESET PULSE TEMPLATES

For E1 applications, the pulse shape is shown in Figure-4 according to the G.703 and the measuring diagram is shown in Figure-5. In internal impedance matching mode, if the cable impedance is 75 Ω, the PULS[3:0] bits (TCF1, 06H) should be set to ‘0000’; if the cable impedance is 120 Ω, the PULS[3:0] bits (TCF1, 06H) should be set to ‘0001’. In external impedance matching mode, for both E1/75 Ω and E1/120 Ω cable impedance, PULS[3:0] should be set to ‘0001’.
For T1 applications, the pulse shape is shown in Figure-6 according to the T1.102 and the measuring diagram is shown in Figure-6. This also meets the requirement of G.703, 2001. The cable length is divided into five grades, and there are five pulse templates used for each of the cable length. The pulse template is selected by PULS[3:0] bits (TCF1, 06H).

TCF1, 06H) should be set to ‘0111’. Table-14 lists these values.

### 3.3.3.2 LBO (LINE BUILD OUT)

To prevent the cross-talk at the far end, the output of TTIP/TRING could be attenuated before transmission for long haul applications. The FCC Part 68 Regulations specifies four grades of attenuation with a step of 7.5 dB. Three LBOs are used to implement the pulse attenuation. The PULS[3:0] bits (TCF1, 06H) are used to select the attenuation grade. Both Table-14 and Table-15 list these values.
3.3.3.3 USER-PROGRAMMABLE ARBITRARY WAVEFORM

When the PULS[3:0] bits are set to ‘11xx’, user-programmable arbitrary waveform generator mode can be used. This allows the transmitter performance to be tuned for a wide variety of line condition or special application.

Each pulse shape can extend up to 4 UIs (Unit Interval), addressed by UI[1:0] bits (TCF3, 08H) and each UI is divided into 16 sub-phases, addressed by the SAMP[3:0] bits (TCF3, 08H). The pulse amplitude of each phase is represented by a binary byte, within the range from +63 to -63, stored in WDAT[6:0] bits (TCF4, 09H) in signed magnitude form. The most positive number +63 (D) represents the positive maximum amplitude of the transmit pulse while the most negative number -63 (D) represents the maximum negative amplitude of the transmit pulse. Therefore, up to 64 bytes are used.

There are twelve standard templates which are stored in an on-chip ROM. User can select one of them as reference and make some changes to get the desired waveform.

User can change the wave shape and the amplitude to get the desired pulse shape. In order to do this, firstly, users can choose a set of waveform value from the following twelve tables, which is the most similar to the desired pulse shape. Table-2, Table-3, Table-4, Table-5, Table-6, Table-7, Table-8, Table-9, Table-10, Table-11, Table-12 and Table-13 list the sample data and scaling data of each of the twelve templates. Then modify the corresponding sample data to get the desired transmit pulse shape.

Secondly, through the value of SCAL[5:0] bits increased or decreased by 1, the pulse amplitude can be scaled up or down at the percentage ratio against the standard pulse amplitude if needed. For different pulse shapes, the value of SCAL[5:0] bits and the scaling percentage ratio are different. The following twelve tables list these values.

Do the followings step by step, the desired waveform can be programmed, based on the selected waveform template:

1. Select the UI by UI[1:0] bits (TCF3, 08H)
2. Specify the sample address in the selected UI by SAMP [3:0] bits (TCF3, 08H)
3. Write sample data to WDAT[6:0] bits (TCF4, 09H). It contains the data to be stored in the RAM, addressed by the selected UI and the corresponding sample address.
4. Set the RW bit (TCF3, 08H) to ‘0’ to implement writing data to RAM, or to ‘1’ to implement read data from RAM
5. Implement the Read from RAM/Write to RAM by setting the DONE bit (TCF3, 08H)

Repeat the above steps until all the sample data are written to or read from the internal RAM.

6. Write the scaling data to SCAL[5:0] bits (TCF2, 07H) to scale the amplitude of the waveform based on the selected standard pulse amplitude

When more than one UI is used to compose the pulse template, the overlap of two consecutive pulses could make the pulse amplitude overflow (exceed the maximum limitation) if the pulse amplitude is not set properly. This overflow is captured by DAC_OV_IS bit (INTS1, 1AH), and, if enabled by the DAC_OV_IM bit (INTM1, 15H), an interrupt will be generated.

The following tables give all the sample data based on the preset pulse templates and LBOs in detail for reference. For preset pulse templates and LBOs, scaling up/down against the pulse amplitude is not supported.

Table-2 Transmit Waveform Value For E1 75 ohm

SCAL[5:0] = 000100 (default), One step change of this value of SCAL[5:0] results in 25% scaling up/down against the pulse amplitude.
3.3.4 TRANSMIT PATH LINE INTERFACE

The transmit line interface consists of TTIP pin and TRING pin. The impedance matching can be realized by the internal impedance matching circuit or the external impedance matching circuit. If T_TERM[2] is set to ‘0’, the internal impedance matching circuit will be selected. In this case, the T_TERM[1:0] bits (TERM, 03H) can be set to choose 75 Ω, 100 Ω, 110 Ω or 120 Ω internal impedance of TTIP/TRING. If T_TERM[2] is set to ‘1’, the internal impedance matching circuit will be disabled. In this case, the external impedance matching circuit will be used to realize the impedance matching. For T1/J1 mode, the external impedance matching circuit for the transmitter is not supported. Figure-8 shows the appropriate external components to connect with the cable. Table-14 is the list of the recommended impedance matching for transmitter.

In hardware control mode, TERM pin can be used to select impedance matching for both receiver and transmitter. If TERM pin is low, external impedance network will be used for impedance matching. If TERM pin is high, internal impedance will be used for impedance matching and PULS[3:0] pins will be set to select the specific internal impedance. Refer to 5 Hardware Control Pin Summary for details.

The TTIP/TRING pins can also be turned into high impedance by setting the THZ bit (TCF1, 06H) to ‘1’. In this state, the internal transmit circuits are still active.

In hardware control mode, TTIP/TRING can be turned into high impedance by pulling THZ pin to high. Refer to 5 Hardware Control Pin Summary for details.

Besides, in the following cases, both TTIP/TRING pins will also become high impedance:

- Loss of MCLK;
- Loss of TCLK (exceptions: Remote Loopback; Transmit internal pattern by MCLK);
- Transmit path power down;
- After software reset; pin reset and power on.

Note: The precision of the resistors should be better than ± 1%

3.3.5 TRANSMIT PATH POWER DOWN

The transmit path can be powered down by setting the T_OFF bit (TCF0, 05H) to ‘1’. In this case, the TTIP/TRING pins are turned into high impedance.

In hardware control mode, the transmit path can be powered down by pulling both PATT1 and PATT0 pins to high. Refer to 5 Hardware Control Pin Summary for details.
3.4 RECEIVE PATH

The receive path consists of Receive Internal Termination, Monitor Gain, Amplitude/Wave Shape Detector, Digital Tuning Controller, Adaptive Equalizer, Data Slicer, CDR (Clock & Data Recovery), Optional Jitter Attenuator, Decoder and LOS/AIS Detector. Refer to Figure-7.

3.4.1 RECEIVE INTERNAL TERMINATION

The impedance matching can be realized by the internal impedance matching circuit or the external impedance matching circuit. If R_TERM[2] is set to ‘0’, the internal impedance matching circuit will be selected. In this case, the R_TERM[1:0] bits (TERM, 03H) can be set to choose 75 Ω, 100 Ω, 110 Ω or 120 Ω internal impedance of RTIP/RRING. If R_TERM[2] is set to “1”, the internal impedance matching circuit will be disabled. In this case, the external impedance matching circuit will be used to realize the impedance matching. Figure-8 shows the appropriate external components to connect with the cable. Table-15 is the list of the recommended impedance matching for receiver.

</tbody>
</table>
In hardware control mode, TERM and PULS[3:0] pins can be used to select impedance matching for both receiver and transmitter. If TERM pin is low, external impedance network will be used for impedance matching. If TERM pin is high, internal impedance will be used for impedance matching and PULS[3:0] pins can be set to select the specific internal impedance. Refer to 5 Hardware Control Pin Summary for details.

### 3.4.2 LINE MONITOR

In both T1/J1 and E1 short haul applications, the non-intrusive monitoring on channels located in other chips can be performed by tapping the monitored channel through a high impedance bridging circuit. Refer to Figure-9 and Figure-11.

After a high resistance bridging circuit, the signal arriving at the RTIP/RRING is dramatically attenuated. To compensate this attenuation, the Monitor Gain can be used to boost the signal by 22 dB, 26 dB and 32 dB, selected by MG[1:0] bits (RCF2, 0CH). For normal operation, the Monitor Gain should be set to 0 dB.

In hardware control mode, MONT pin can be used to set the Monitor Gain. When MONT pin is low, the Monitor Gain is 0 dB. When MONT pin is high, the Monitor Gain is 26 dB. Refer to 5 Hardware Control Pin Summary for details.

Note that LOS indication is not supported if the device is operated in Line Monitor Mode.
3.4.3 ADAPTIVE EQUALIZER

The Adaptive Equalizer can remove most of the signal distortion due to intersymbol interference caused by cable attenuation. It can be enabled or disabled by setting EQ_ON bit to ‘1’ or ‘0’ (RCF1, 0BH).

When the adaptive equalizer is out of range, EQ_S bit (STAT0, 17H) will be set to ‘1’ to indicate the status of equalizer. If EQ_IES bit (INTES, 16H) is set to ‘1’, any changes of EQ_S bit will generate an interrupt and EQ_IS bit (INTS0, 19H) will be set to ‘1’ if it is not masked. If EQ_IES is set to ‘0’, only the ‘0’ to ‘1’ transition of the EQ_S bit will generate an interrupt and EQ_IS bit will be set to ‘1’ if it is not masked. The EQ_IS bit will be reset after being read.

The Amplitude/wave shape detector keeps on measuring the amplitude/wave shape of the incoming signals during an observation period. This observation period can be 32, 64, 128 or 256 symbol periods, as selected by UPDW[1:0] bits (RCF2, 0CH). A shorter observation period allows quicker responses to pulse amplitude variation while a longer observation period can minimize the possible overshoots. The default observation period is 128 symbol periods.

Based on the observed peak value for a period, the equalizer will be adjusted to achieve a normalized signal. LATT[4:0] bits (STAT1, 18H) indicate the signal attenuation introduced by the cable in approximately 2 dB per step.

3.4.4 RECEIVE SENSITIVITY

For short haul application, the Receive Sensitivity for both E1 and T1/J1 is -10 dB. For long haul application, the receive sensitivity is -43 dB for E1 and -36 dB for T1/J1.

When the chip is configured by hardware, the short haul or long haul operating mode can be selected by setting EQ pin. For short haul mode, the receive sensitivity is -10 dB for E1 and -36 dB for T1/J1. Refer to 5 Hardware Control Pin Summary for details.

3.4.5 DATA SLICER

The Data Slicer is used to generate a standard amplitude mark or a space according to the amplitude of the input signals. The threshold can be 40%, 50%, 60% or 70%, as selected by the SLICE[1:0] bits (RCF2, 0CH). The output of the Data Slicer is forwarded to the CDR (Clock & Data Recovery) unit or to the RDP/RDN pins directly if the CDR is disabled.

3.4.6 CDR (CLOCK & DATA RECOVERY)

The CDR is used to recover the clock and data from the received signal. The recovered clock tracks the jitter in the data output from the Data Slicer and keeps the phase relationship between data and clock during the absence of the incoming pulse. The CDR can also be by-passed in the Dual Rail mode. When CDR is by-passed, the data from the Data Slicer is output to the RDP/RDN pins directly.

3.4.7 DECODER

In T1/J1 applications, the R_MD[1:0] bits (RCF0, 0AH) is used to select the AMI decoder or BBZS decoder. In E1 applications, the R_MD[1:0] bits (RCF0, 0AH) are used to select the AMI decoder or HDB3 decoder.

When the chip is configured by hardware, the operation mode of receive and transmit path can be selected by setting RXTXM1 and RXTXM0 pins. Refer to 5 Hardware Control Pin Summary for details.
3.4.8 RECEIVE PATH SYSTEM INTERFACE

The receive path system interface consists of RCLK pin, RD/RDP pin and RDN pin. In E1 mode, the RCLK outputs a recovered 2.048 MHz clock. In T1/J1 mode, the RCLK outputs a recovered 1.544 MHz clock. The received data is updated on the RD/RDP and RDN pins on the active edge of RCLK. The active edge of RCLK can be selected by the RCLK_SEL bit (RCF0, 0AH). And the active level of the data on RD/RDP and RDN can be selected by the RD_INV bit (RCF0, 0AH).

In hardware control mode, only the active edge of RCLK can be selected. If RCLKE is set to high, the falling edge will be chosen as the active edge of RCLK. If RCLKE is set to low, the rising edge will be chosen as the active edge of RCLK. The active level of the data on RD/RDP and RDN is the same as that in software control mode.

The received data can be output to the system side in two different ways: Single Rail or Dual Rail, as selected by R_MD bit [1] (RCF0, 0AH). In Single Rail mode, only RD pin is used to output data and the RDN/CV pin is used to report the received errors. In Dual Rail Mode, both RDP pin and RDN pin are used for outputting data.

In the receive Dual Rail mode, the CDR unit can be by-passed by setting R_MD[1:0] to ‘11’ (binary). In this situation, the output data from the Data Slicer will be output to the RDP/RDN pins directly, and the RCLK outputs the exclusive OR (XOR) of the RDP and RDN. This is called receiver slicer mode. In this case, the transmit path is still operating in Dual Rail mode.

3.4.9 RECEIVE PATH POWER DOWN

The receive path can be powered down by setting R_OFF bit (RCF0, 0AH) to ‘1’. In this case, the RCLK, RD/RDP, RDN and LOS will be logic low.

In hardware control mode, receiver power down can be selected by pulling RPD pin to high. Refer to 5 Hardware Control Pin Summary for more details.

3.5 JITTER ATTENUATOR

There is one Jitter Attenuator in the IDT82V2081. The Jitter Attenuator can be deployed in the transmit path or the receive path, and can also be disabled. This is selected by the JACF[1:0] bits (JACF, 04H).

In hardware control mode, Jitter Attenuator position, bandwidth and the depth of FIFO can be selected by JA[1:0] pins. Refer to 5 Hardware Control Pin Summary for details.

3.5.1 JITTER ATTENUATION FUNCTION DESCRIPTION

The Jitter Attenuator is composed of a FIFO and a DPLL, as shown in Figure-11. The FIFO is used as a pool to buffer the jittered input data, then the data is clocked out of the FIFO by a de-jittered clock. The depth of the FIFO can be 32 bits, 64 bits or 128 bits, as selected by the JADP[1:0] bits (JACF, 04H). In hardware control mode, the depth of FIFO can be selected by JA[1:0] pins. Refer to 5 Hardware Control Pin Summary for details. Consequently, the constant delay of the Jitter Attenuator will be 16 bits, 32 bits or 64 bits. Deeper FIFO can tolerate larger jitter, but at the cost of increasing data latency time.

![Figure-11 Jitter Attenuator](image-url)

In E1 applications, the Corner Frequency of the DPLL can be 0.9 Hz or 6.8 Hz, as selected by the JABW bit (JACF, 04H). In T1/J1 applications, the Corner Frequency of the DPLL can be 1.25 Hz or 5.00 Hz, as selected by the JABW bit (JACF, 04H). The lower the Corner Frequency is, the longer time is needed to achieve synchronization.

When the incoming data moves faster than the outgoing data, the FIFO will overflow. This overflow is captured by the JAOV_IS bit (INTS1, 1AH). If the incoming data moves slower than the outgoing data, the FIFO will underflow. This underflow is captured by the JAUD_IS bit (INTS1, 1AH). For some applications that are sensitive to data corruption, the JA limit mode can be enabled by setting JA_LIMIT bit (JACF, 04H) to ‘1’. In the JA limit mode, the speed of the outgoing data will be adjusted automatically when the FIFO is close to its full or emptiness. The criteria of starting speed adjustment are shown in Table-16. The JA limit mode can reduce the possibility of FIFO overflow and underflow, but the quality of jitter attenuation is deteriorated.
### 3.5.2 JITTER ATTENUATOR PERFORMANCE

The performance of the Jitter Attenuator in the IDT82V2081 meets the ITU-T I.431, G.703, G.736-739, G.823, G.824, ETSI 300011, ETSI TBR12/13, AT&T TR62411 specifications. Details of the Jitter Attenuator performance is shown in Table-63 Jitter Tolerance and Table-64 Jitter Attenuator Characteristics.

### 3.6 LOS AND AIS DETECTION

#### 3.6.1 LOS DETECTION

The Loss of Signal Detector monitors the amplitude of the incoming signal level and pulse density of the received signal on RTIP and RRING.

- **LOS declare (LOS=1)**
  
  A LOS is detected when the incoming signal has “no transitions”, i.e., when the signal level is less than Q dB below nominal for N consecutive pulse intervals. Here N is defined by LAC bit (MAINT0, 0DH). LOS will be declared by pulling LOS pin to high (LOS=1) and LOS interrupt will be generated if it is not masked.

  Note that LOS indication is not supported if the device is operated in Line Monitor Mode. Refer to 3.4.2 Line Monitor.

- **LOS clear (LOS=0)**
  
  The LOS is cleared when the incoming signal has “transitions”, i.e., when the signal level is greater than P dB below nominal and has an average pulse density of at least 12.5% for M consecutive pulse intervals, starting with the receipt of a pulse. Here M is defined by LAC bit (MAINT0, 0DH). LOS status is cleared by pulling LOS pin to low.

#### 3.6.2 LOS detect level threshold

- In short haul mode, the amplitude threshold Q is fixed on 800 mVpp, while P=Q+200 mVpp (200 mVpp is the LOS level detect hysteresis).

- In long haul mode, the value of Q can be selected by LOS[4:0] bit (RCF1, 0BH), while P=Q+4 dB (4 dB is the LOS level detect hysteresis). The Table-30 LOS[4:0] default value is 10101 (-46 dB).

- When the chip is configured by hardware, the LOS detect level is fixed if the IDT82V2081 operates in long haul mode. It is -46 dB (E1) and -38 dB (T1/J1).

#### Criteria for declare and clear of a LOS detect

- The detection supports ANSI T1.231 and I.431 for T1/J1 mode and G.775 and ETSI 300233/I.431 for E1 mode. The criteria can be selected by LAC bit (MAINT0, 0DH) and T1E1 bit (GCF, 02H).

- Table-17 and Table-18 summarize LOS declare and clear criteria for both short haul and long haul application.

#### All Ones output during LOS

- On the system side, the RDP/RDN will reflect the input pulse “transition” at the RTIP/RRING side and output recovered clock (but the quality of the output clock can not be guaranteed when the input level is lower than the maximum receive sensitivity) when AISE bit (MAINT0, 0DH) is 0; or output All Ones as AIS when AISE bit (MAINT0, 0DH) is 1. In this case, RCLK output is replaced by MCLK.

- On the line side, the TTIP/TRING will output All Ones as AIS when ATAO bit (MAINT0, 0DH) is 1. The All Ones pattern uses MCLK as the reference clock.

- LOS indicator is always active for all kinds of loopback modes.

### 3.6.2 AIS DETECTION

The Alarm Indication Signal can be detected by the IDT82V2081 when the Clock & Data Recovery unit is enabled. The status of AIS detection is reflected in the AIS_S bit (STAT0, 17H). In T1/J1 applications, the criteria for declaring/clearing AIS detection are in compliance with the ANSI T1.231. In E1 applications, the criteria for declaring/clearing AIS detection comply with the ITU G.775 or the ETSI 300233, as selected by the LAC bit (MAINT0, 0DH). Table-19 summarizes different criteria for AIS detection Declaring/Clearing.

3.7 TRANSMIT AND DETECT INTERNAL PATTERNS

The internal patterns (All Ones, All Zeros, PRBS/QRSS pattern and Activate/Deactivate Loopback Code) will be generated and detected by IDT82V2081. TCLK is used as the reference clock by default. MCLK can also be used as the reference clock by setting the PATT_CLK bit (MAINT0, 0DH) to ‘1’.

If the PATT_CLK bit (MAINT0, 0DH) is set to ‘0’ and the PATT[1:0] bits (MAINT0, 0DH) are set to ‘00’, the transmit path will operate in normal mode.

When the chip is configured by hardware, the transmit path will operate in normal mode by setting PATT[1:0] pins to ‘00’. Refer to 5 Hardware Control Pin Summary for details.

3.7.1 TRANSMIT ALL ONES

In transmit direction, the All Ones data can be inserted into the data stream when the PATT[1:0] bits (MAINT0, 0DH) are set to ‘01’. The transmit data stream is output from TTIP/TRING. In this case, either TCLK or MCLK can be used as the transmit clock, as selected by the PATT_CLK bit (MAINT0, 0DH).

In hardware control mode, the All Ones data can be inserted into the data stream in transmit direction by setting PATT[1:0] pins to ‘01’. Refer to 5 Hardware Control Pin Summary for details.

3.7.2 TRANSMIT ALL ZEROS

If the PATT_CLK bit (MAINT0, 0DH) is set to ‘1’, the All Zeros will be inserted into the transmit data stream when the PATT[1:0] bits (MAINT0, 0DH) are set to ‘00’.

3.7.3 PRBS/QRSS GENERATION AND DETECTION

A PRBS/QRSS pattern will be generated in the transmit direction and detected in the receive direction by IDT82V2081. The QRSS is 2^{20}-1 for T1/J1 applications and the PRBS is 2^{15}-1 for E1 applications, with maximum zero restrictions according to AT&T TR624111 and ITU-T O.151.

When the PATT[1:0] bits (MAINT0, 0DH) are set to ‘10’, the PRBS/QRSS pattern will be transmitted into the transmit data stream with the MSB first. The PRBS/QRSS pattern will be transmitted directly or invertedly.

In hardware control mode, the PRBS data will be generated and inserted into the transmit data stream by setting PATT[1:0] pins to ‘10’. Refer to 5 Hardware Control Pin Summary for details.

The PRBS/QRSS in the received data stream will be monitored. If the PRBS/QRSS has reached synchronization status, the PRBS_S bit (STAT0, 17H) will be set to ‘1’, even in the presence of a logic error rate less than or equal to 10^{-1}. The criteria for setting/clearing the PRBS_S bit are shown in Table-20.

<table>
<thead>
<tr>
<th>PRBS/QRSS Detection</th>
<th>6 or less than 6 bit errors detected in a 64 bits hopping window.</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRBS/QRSS Missing</td>
<td>More than 6 bit errors detected in a 64 bits hopping window.</td>
</tr>
</tbody>
</table>

PRBS data can be inverted through setting the PRBS_INV bit (MAINT0, 0DH).

Any change of PRBS_S bit will be captured by PRBS_IS bit (INTS0, 19H). The PRBS_IES bit (INTES, 16H) can be used to determine whether the ‘0’ to ‘1’ change of PRBS_S bit will be captured by the PRBS_IS bit or any changes of PRBS_S bit will be captured by the PRBS_IS bit. When the PRBS_IS bit is ‘1’, an interrupt will be generated if the PRBS_IM bit (INTM0, 14H) is set to ‘1’.

The received PRBS/QRSS logic errors can be counted in a 16-bit counter if the ERR_SEL[1:0] bits (MAINT6, 13H) are set to ‘00’. Refer to 3.9 Error Detection/Counting And Insertion for the operation of the error counter.

3.8 LOOPBACK

To facilitate testing and diagnosis, the IDT82V2081 provides four different loopback configurations: Analog Loopback, Digital Loopback, Remote Loopback and Inband Loopback.

3.8.1 ANALOG LOOPBACK

When the ALP bit (MAINT1, 0EH) is set to ‘1’, the chip is configured in Analog Loopback mode. In this mode, the transmit signals are looped back to the Receiver Internal Termination in the receive path then output from RCLK, RD, RDP/RDN. At the same time, the transmit signals are still output to TTIP/TRING in transmit direction. The all-ones pattern can be generated during analog loopback. Figure-13 shows the process.

3.8.2 DIGITAL LOOPBACK

When the DLP bit (MAINT1, 0EH) is set to ‘1’, the chip is configured in Digital Loopback mode. In this mode, the transmit signals are looped back to the jitter attenuator (if enabled) and decoder in receive path, then output from RCLK, RD, RDP/RDN. At the same time, the transmit signals are still output to TTIP/TRING in transmit direction. Figure-14 shows the process.

Both Analog Loopback mode and Digital Loopback mode allow the sending of the internal patterns (All Ones, All Zeros, PRBS, etc.) which will overwrite the transmit signals. In this case, either TCLK or MCLK can be used as the reference clock for internal patterns transmission.

In hardware control mode, Digital Loopback can be selected by setting LP[1:0] pins to ‘10’.

3.8.3 REMOTE LOOPBACK

When the RLP bit (MAINT1, 0EH) is set to ‘1’, the chip is configured in Remote Loopback mode. In this mode, the recovered clock and data output from Clock and Data Recovery on the receive path is looped back to the jitter attenuator (if enabled) and Waveform Shaper in transmit path. Figure-15 shows the process.

In hardware control mode, Remote Loopback can be selected by setting LP[1:0] pins to ‘11’.
Figure-13  Analog Loopback

Figure-14  Digital Loopback
3.8.4 INBAND LOOPBACK

When PATT[1:0] bits (MAINT0, 0DH) are set to ‘11’, the IDT82V2081 is configured in Inband Loopback mode. In this mode, an unframed activate/Deactivate Loopback Code is generated repeatedly in transmit direction per ANSI T1. 403 which overwrite the transmit signals. In receive direction, the framed or unframed code is detected per ANSI T1. 403, even in the presence of $10^{-2}$ bit error rate.

If the Automatic Remote Loopback is enabled by setting ARLP bit (MAINT1, 0EH) to ‘1’, the chip will establish/demolish the Remote Loopback based on the reception of the Activate Loopback Code/Deactivate Loopback Code for 5.1 s. If the ARLP bit (MAINT1, 0EH) is set to ‘0’, the Remote Loopback can also be demolished forcibly.

3.8.4.1 TRANSMIT ACTIVATE/DEACTIVATE LOOPBACK CODE

The pattern of the transmit Activate/Deactivate Loopback Code is defined by the TIBLB[7:0] bits (MAINT3, 10H). Whether the code represents an Activate Loopback Code or a Deactivate Loopback Code is judged by the far end receiver. The length of this pattern ranges from 5 bits to 8 bits, as selected by the TIBLB_L[1:0] bits (MAINT2, 0FH). The pattern can be programmed to 6-bit-long or 8-bit-long respectively by repeating itself if it is 3-bit-long or 4-bit-long.

The local transmit activate/deactivate code setting should be the same as the receive code setting in the remote end. It is the same thing for the other way round.

3.8.4.2 RECEIVE ACTIVATE/DEACTIVATE LOOPBACK CODE

The pattern of the receive Activate Loopback Code is defined by the RIBLBA[7:0] bits (MAINT4, 11H). The length of this pattern ranges from 5 bits to 8 bits, as selected by the RIBLBA_L[1:0] bits (MAINT2, 0FH). The pattern can be programmed to 6-bit-long or 8-bit-long respectively by repeating itself if it is 3-bit-long or 4-bit-long.

After the Activate Loopback Code has been detected in the receive data for more than 30 ms (in E1 mode) / 40 ms (in T1/J1 mode), the IBLBA_S bit (STAT0, 17H) will be set to ‘1’ to declare the reception of the Activate Loopback Code.

After the Deactivate Loopback Code has been detected in the receive data for more than 30 ms (in E1 mode) / 40 ms (in T1/J1 mode), the IBLBD_S bit (STAT0, 17H) will be set to ‘1’ to declare the reception of the Deactivate Loopback Code.

When the IBLBA_IES bit (INTES, 16H) is set to ‘0’, only the ‘0’ to ‘1’ transition of the IBLBA_S bit will generate an interrupt and set the IBLBA_IS bit (INTS0, 19H) to ‘1’. The IBLBA_IS bit will be reset to ‘0’ after being read.

When the IBLBD_IES bit (INTES, 16H) is set to ‘0’, only the ‘0’ to ‘1’ transition of the IBLBD_S bit will generate an interrupt and set the IBLBD_IS bit (INTS0, 19H) to ‘1’. The IBLBD_IS bit will be reset to ‘0’ after being read.

3.8.4.3 AUTOMATIC REMOTE LOOPBACK

When ARLP bit (MAINT1, 0EH) is set to ‘1’, the IDT82V2081 is configure
5.1 s, the Remote Loopback (shown as Figure-15) will be established automatically, and the RLP_S bit (STAT1, 18H) will be set to ‘1’ to indicate the establishment of the Remote Loopback. The IBLBA_S bit (STAT0, 17H) is set to ‘1’ to generate an interrupt. In this case, the Remote Loopback mode will still be kept even if the receiver stop receiving the Activate Loopback Code.

If the Deactivate Loopback Code has been detected in the receive data for more than 5.1 s, the Remote Loopback will be demolished automatically, and the RLP_S bit (STAT1, 18H) will set to ‘0’ to indicate the demolition of the Remote Loopback. The IBLBD_S bit (STAT0, 17H) is set to ‘1’ to generate an interrupt.

The Remote Loopback can also be demolished forcibly by setting ARLP bit (MAINT1, 0EH) to ‘0’.
3.9 ERROR DETECTION/COUNTING AND INSERTION

3.9.1 DEFINITION OF LINE CODING ERROR

The following line encoding errors can be detected and counted by the IDT82V2081:

- **Received Bipolar Violation (BPV) Error:** In AMI coding, when two consecutive pulses of the same polarity are received, a BPV error is declared.

- **HDB3/B8ZS Code Violation (CV) Error:** In HDB3/B8ZS coding, a CV error is declared when two consecutive BPV errors are detected, and the pulses that have the same polarity as the previous pulse are not the HDB3/B8ZS zero substitution pulses.

- **Excess Zero (EXZ) Error:** There are two standards defining the EXZ errors: ANSI and FCC. The EXZ_DEF bit (MAINT6, 13H) chooses which standard will be adopted by the chip to judge the EXZ error. Table-21 shows definition of EXZ. In hardware control mode, only ANSI standard is adopted.

<table>
<thead>
<tr>
<th>EXZ Definition</th>
<th>ANSI</th>
<th>FCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMI</td>
<td>More than 15 consecutive 0s are detected</td>
<td>More than 80 consecutive 0s are detected</td>
</tr>
<tr>
<td>HDB3</td>
<td>More than 3 consecutive 0s are detected</td>
<td>More than 3 consecutive 0s are detected</td>
</tr>
<tr>
<td>B8ZS</td>
<td>More than 7 consecutive 0s are detected</td>
<td>More than 7 consecutive 0s are detected</td>
</tr>
</tbody>
</table>

3.9.2 ERROR DETECTION AND COUNTING

Which type of the receiving errors (Received CV/BPV errors, excess zero errors and PRBS logic errors) will be counted is determined by ERR_SEL[1:0] bits (MAINT6, 13H). Only one type of receiving error can be counted at a time except that when the ERR_SEL[1:0] bits are set to ‘11’, both CV/BPV and EXZ errors will be detected and counted.

The selected type of receiving errors is counted in an internal 16-bit Error Counter. Once an error is detected, an error interrupt which is indicated by corresponding bit in (INTS1, 1AH) will be generated if it is not masked. This Error Counter can be operated in two modes: Auto Report Mode and Manual Report Mode, as selected by the CNT_MD bit (MAINT6, 13H). In Single Rail mode, once BPV or CV errors are detected, the CV pin will be driven to high for one RCLK period.

- **Auto Report Mode**

In Auto Report Mode, the internal counter starts to count the received errors when the CNT_MD bit (MAINT6, 13H) is set to ‘1’. A one-second timer is used to set the counting period. The received errors are counted within one second. If the one-second timer expires, the value in the internal counter will be transferred to (CNT0, 1BH) and (CNT1, 1CH), then the internal counter will be reset and start to count received errors for the next second. The errors occurred during the transfer will be accumulated to the next round. The expiration of the one-second timer will set TMOV_IS bit (INTS1, 1AH) to ‘1’, and will generate an interrupt if the TIMER_IM bit (INTM1, 15H) is set to ‘0’. The TMOV_IS bit (INTS1, 1AH) will be cleared after the interrupt register is read. The content in the (CNT0, 1BH) and (CNT1, 1CH) should be read within the next second. If the counter overflows, a counter overflow interrupt which is indicated by CNT_OV_IS bit (INTS1, 1AH) will be generated if it is not masked by CNT_IM bit (INTM1, 15H).
- **Manual Report Mode**

  In Manual Report Mode, the internal Error Counter starts to count the received errors when the CNT_MD bit (MAINT6, 13H) is set to ‘0’. When there is a ‘0’ to ‘1’ transition on the CNT_TRF bit (MAINT6, 13H), the data in the counter will be transferred to (CNT0, 1BH) and (CNT1, 1CH), then the counter will be reset. The errors occurred during the transfer will be accumulated to the next round. If the counter overflows, a counter overflow interrupt indicated by CNT_OV_IS bit (INTS1, 1AH) will be generated if it is not masked by CNT_IM bit (INTM1, 15H).

![Figure-17 Manual Report Mode](image)

**Note:** It is recommended that users should do the followings within next round of error counting: Read the data in CNT0 and CNT1; Reset CNT_TRF bit for the next ‘0’ to ‘1’ transition on this bit.

### 3.9.3 Bipolar Violation and PRBS Error Insertion

Only when three consecutive ‘1’s are detected in the transmit data stream, will a ‘0’ to ‘1’ transition on the BPV_INS bit (MAINT6, 13H) generate a bipolar violation pulse, and the polarity of the second ‘1’ in the series will be inverted.

A ‘0’ to ‘1’ transition on the EER_INS bit (MAINT6, 13H) will generate a logic error during the PRBS/QRSS transmission.

### 3.10 Line Driver Failure Monitoring

The transmit driver failure monitor can be enabled or disabled by setting DFM_OFF bit (TCF1, 06H). If the transmit driver failure monitor is enabled, the transmit driver failure will be captured by DF_S bit (STAT0, 17H). The transition of the DF_S bit is reflected by DF_IS bit (INTS0, 19H), and, if enabled by DF_IM bit (INTM0, 14H), will generate an interrupt. When there is a short circuit on the TTIP/TRING port, the output current will be limited to 100 mA (typical), and an interrupt will be generated.

In hardware control mode, the transmit driver failure monitor is always enabled.
### 3.11 MCLK AND TCLK

#### 3.11.1 MASTER CLOCK (MCLK)

MCLK is an independent, free-running reference clock. MCLK is 1.544 MHz for T1/J1 applications and 2.048 MHz in E1 mode. This reference clock is used to generate several internal reference signals:

- Timing reference for the integrated clock recovery unit.
- Timing reference for the integrated digital jitter attenuator.
- Timing reference for microcontroller interface.
- Generation of RCLK signal during a loss of signal condition if AIS is enabled.
- Reference clock during Transmit All Ones, PRBS/QRSS pattern and Inband Loopback code if it is selected as the reference clock. For ATAO and AIS, MCLK is always used as the reference clock.
- Reference clock during Transmit All Ones (TAO) condition or sending PRBS/QRSS in hardware control mode.

Figure-18 shows the chip operation status in different conditions of MCLK and TCLK. The missing of MCLK will set the TTIP/TRING to high impedance state.

#### 3.11.2 TRANSMIT CLOCK (TCLK)

TCLK is used to sample the transmit data on TD/TDP and TDN. The active edge of TCLK can be selected by the TCLK_SEL bit (TCF0, 05H). During Transmit All Ones, PRBS/QRSS patterns or Inband Loopback Code, either TCLK or MCLK can be used as the reference clock. This is selected by the PATT_CLK bit (MAINT0, 0DH).

But for Automatic Transmit All Ones and AIS, only MCLK is used as the reference clock and the PATT_CLK bit is ignored. In Automatic Transmit All Ones condition, the ATAO bit (MAINT0, 0DH) is set to ‘1’. In AIS condition, the AISE bit (MAINT0, 0DH) is set to ‘1’.

If TCLK has been missing for more than 70 MCLK cycles, TCLK_LOS bit (STAT0, 17H) will be set, and the TTIP/TRING will become high impedance if the chip is not used for remote loopback or is not using MCLK to transmit internal patterns (TAOS, All Zeros, PRBS and in-band loopback code). When TCLK is detected again, TCLK_LOS bit (STAT0, 17H) will be cleared. The reference frequency to detect a TCLK loss is derived from MCLK.

---

**Figure-18 TCLK Operation Flowchart**
3.12 MICROCONTROLLER INTERFACES

The microcontroller interface provides access to read and write the registers in the device. The chip supports serial microcontroller interface and two kinds of parallel microcontroller interface: Motorola multiplexed mode and Intel multiplexed mode. Different microcontroller interfaces can be selected by setting MODE[1:0] pins to different values. Refer to MODE1 and MODE0 in pin description and Microcontroller Interface Timing Characteristics for details.

3.12.1 PARALLEL MICROCONTROLLER INTERFACE

The interface is compatible with Motorola or Intel microcontroller. When MODE[1:0] pins are set to ‘10’, Parallel-Multiplexed-Motorola interface is selected. When MODE[1:0] pins are set to ‘11’, Parallel-Multiplexed-Intel Interface is selected.

3.12.2 SERIAL MICROCONTROLLER INTERFACE

When MODE[1:0] pins are set to ‘01’, Serial Interface is selected. In this mode, the registers are programmed through a 16-bit word which contains an 8-bit address/command byte (5 address bits A0~A4 and bit R/W) and an 8-bit data byte (D0~D7). When bit R/W is ‘1’, data is read out from pin SDO. When bit R/W is ‘0’, data is written into SDI pin. Refer to Figure-19.

3.13 INTERRUPT HANDLING

All kinds of interrupt of the IDT82V2081 are indicated by the INT pin. When the INT_PIN[0] bit (GCF, 02H) is ‘0’, the INT pin is open drain active low, with a 10 KΩ external pull-up resistor. When the INT_PIN[1:0] bits (GCF, 02H) are ‘01’, the INT pin is push-pull active low; when the INT_PIN[1:0] bits are ‘10’, the INT pin is push-pull active high.

An active level on the INT pin represents an interrupt of the IDT82V2081.

The interrupt event is captured by the corresponding bit in the Interrupt Status Register (INTS0, 19H) or (INTS1, 1AH). Every kind of interrupt can be enabled/disabled individually by the corresponding bit in the register (INTM0, 14H) or (INTM1, 15H). Some event is reflected by the corresponding bit in the Status Register (STAT0, 17H) or (STAT1, 18H), and the Interrupt Trigger Edge Selection Register can be used to determine how the Status Register sets the Interrupt Status Register.

After the Interrupt Status Register (INTS0, 19H) or (INTS1, 1AH) is read, the INT pin become inactive.

There are totally fourteen kinds of events that could be the interrupt source:

1. LOS Detected
2. AIS Detected
3. Driver Failure Detected
4. TCLK Loss
5. Synchronization Status of PRBS
6. PRBS Error Detected
7. Code Violation Received
8. Excessive Zeros Received
9. JA FIFO Overflow/Underflow
10. Inband Loopback Code Status
11. Equalizer Out of Range
12. One-Second Timer Expired
13. Error Counter Overflow
14. Arbitrary Waveform Generator Overflow

Table-22 is a summary of all kinds of interrupt and the associated Status bit, Interrupt Status bit, Interrupt Trigger Edge Selection bit and Interrupt Mask bit.

3.14 5V TOLERANT I/O PINS

All digital input pins will tolerate 5.0 ± 10% volts and are compatible with TTL logic.

3.15 RESET OPERATION

The chip can be reset in two ways:
- Software Reset: Writing to the **RST** register (01H) will reset the chip in 1 us.
- Hardware Reset: Asserting the **RST** pin low for a minimum of 100 ns will reset the chip.

During Hardware Reset, the device requires an active clock on MCLK. For T1/J1 operation, bit T1E1(GCF0) is set after reset.

Before accessing any other registers a delay of 50 us is required to allow the internal clocking to be settled.

After reset, all drivers output are in high impedance state, all the internal flip-flops are reset, and all the registers are initialized to default values.

When performing a software reset, the T1E1 bit (GCF0) will not be reset and stay with the set value.

3.16 POWER SUPPLY

This chip uses a single 3.3 V power supply.
# Programming Information

## 4 Register List and Map

The registers banks include control registers, status registers and counter registers.

### Table-23 Register List and Map

</table>
| SCAL[5:0] | 5-0 | 100001  | SCAL specifies a scaling factor to be applied to the amplitude of the user-programmable arbitrary pulses which is to be transmitted if needed. The default value of SCAL[5:0] is ‘100001’. Refer to 3.3.3.3 User-Programmable Arbitrary Waveform.  
= 110110: Default value for T1 0~133 ft, T1 133~266 ft, T1 266~399 ft, T1 399~533 ft, T1 533~655 ft, J1 0~655 ft, DS1 0dB LBO. One step change of this value results in 2% scaling up/down against the pulse amplitude.  
= 010001: Default value for DS1 -7.5 dB LBO. One step change of this value results in 6.25% scaling up/down against the pulse amplitude.  
= 001000: Default value for DS1 -15.0 dB LBO. One step change of this value results in 12.5% scaling up/down against the pulse amplitude.  
= 000100: Default value for DS1 -22.5 dB LBO. One step change of this value results in 25% scaling up/down against the pulse amplitude.  
| 100001: Default value for 75$\Omega$ and 120$\Omega$. One step change of this value results in 3% scaling up/down against the pulse amplitude. |

  - 58 mA

1. Power consumption includes power consumption on device and load. Digital levels are 10% of the supply rails and digital outputs driving a 50 \(\text{pF}\) capacitive load.
2. Maximum power consumption over the full operating temperature and power supply voltage range.
3. In short haul mode, if internal impedance matching is chosen, E1 75 \(\Omega\) power dissipation values are measured with template PULS\([3:0]\) = 0000; E1 120 \(\Omega\) power dissipation values are measured with template PULS\([3:0]\) = 0001; T1 power dissipation values are measured with template PULS\([3:0]\) = 0110; J1 power dissipation values are measured with template PULS\([3:0]\) = 0111.

1. Relative to nominal frequency, MCLK= ± 100 ppm
2. RCLK duty cycle widths will vary depending on extent of received pulse jitter displacement. Maximum and minimum RCLK duty cycles are for worst case jitter conditions (0.2 UI displacement for E1 per ITU G.823).
3. For all digital outputs. C load = 15 pF

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.

2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.

3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.

5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

   "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.

6. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.

7. Although Renesas Electronics endeavors to improve the quality and reliability of its semiconductor products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.

8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated or administered by the governments of any countries asserting jurisdiction over the parties or transactions.

10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.

11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.
