Description

The 8T49N242 has one fractional-feedback PLL that can be used as a jitter attenuator and frequency translator. It is equipped with four integer output dividers, allowing the generation of up to four output frequencies, ranging from 8kHz to 1GHz. These frequencies are completely independent of the input reference frequencies, and the crystal reference frequency. The device places virtually no constraints on input to output frequency conversion, supporting all FEC rates, including the new revision of ITU-T Recommendation G.709 (2009), most with 0ppm conversion error. The outputs may select among LVPECL, LVDS, HCSL or LVCMOS output levels.

This makes it ideal to be used in any frequency synthesis application, including 1G, 10G, 40G and 100G Synchronous Ethernet, OTN, and SONET/SDH, including ITU-T G.709 (2009) FEC rates.

The 8T49N242 accepts up to two differential or single-ended input clocks and a fundamental-mode crystal input. The internal PLL can lock to either of the input reference clocks or just to the crystal to behave as a frequency synthesizer. The PLL can use the second input for redundant backup of the primary input reference, but in this case, both input clock references must be related in frequency.

The device supports hitless reference switching between input clocks. The device monitors both input clocks for Loss of Signal (LOS), and generates an alarm when an input clock failure is detected. Automatic and manual hitless reference switching options are supported. LOS behavior can be set to support gapped or un-gapped clocks.

The 8T49N242 supports holdover. The holdover has an initial accuracy of ±50ppb from the point where the loss of all applicable input reference(s) has been detected. It maintains a historical average operating point for the PLL that may be returned to in holdover at a limited phase slope.

The PLL has a register-selectable loop bandwidth from 0.2Hz to 6.4kHz.

The device supports Output Enable & Clock Select inputs and Lock, Holdover & LOS status outputs.

The device is programmable through an I^2C interface. It also supports I^2C master capability to allow the register configuration to be read from an external EEPROM.

Programming with IDT's Timing Commander software is recommended for optimal device performance. Factory pre-programmed devices are also available.

Typical Applications

- OTN or SONET / SDH equipment
- Gigabit and Terabit IP switches / routers including Synchronous Ethernet
- Video broadcast

Features

- Supports SDH/SONET and Synchronous Ethernet clocks including all FEC rate conversions
- 0.35ps RMS Typical Jitter (including spurs): 12kHz to 20MHz
- Operating Modes: Synthesizer, Jitter Attenuator
- Operates from a 10MHz to 50MHz fundamental-mode crystal or a 10MHz to 125MHz external oscillator
- Initial holdover accuracy of ±50ppb.
- Accepts up to 2 LVPECL, LVDS, LVHSTL or LVCMOS input clocks
  - Accepts frequencies ranging from 8kHz to 875MHz
  - Auto and manual clock selection with hitless switching
  - Clock input monitoring including support for gapped clocks
- Phase-slope limiting and fully hitless switching options to control output clock phase transients
- Generates four LVPECL / LVDS / HCSL or eight LVCMOS output clocks
  - Output frequencies ranging from 8kHz up to 1.0GHz (differential)
  - Output frequencies ranging from 8kHz to 250MHz (LVCMOS)
  - Integer divider ranging from +4 to +786,420 for each output
  - Programmable loop bandwidth settings from 0.2Hz to 6.4kHz
  - Optional fast-lock function
- Four General Purpose I/O pins with optional support for status & control:
  - Two Output Enable control inputs provide control over the four clocks
  - Manual clock selection control input
  - Lock, Holdover and Loss-of-Signal alarm outputs
  - Open-drain Interrupt pin
- Register programmable through I^2C or via external I^2C EEPROM
- Full 2.5V or 3.3V supply modes, 1.8V support for LVCMOS outputs, GPIO and control pins
- -40°C to 85°C ambient operating temperature
- Package: 40-VFQFPN, lead-free (RoHS 6)

NOTE 2: This specification does not apply to the OSCI or OSCO pins.
Principles of Operation

The 8T49N242 can be locked to either of the input clocks and generate a wide range of synchronized output clocks.

It could be used for example in either the transmit or receive path of Synchronous Ethernet equipment.

The 8T49N242 accepts up to two differential or single-ended input clocks ranging from 8kHz up to 875MHz. It generates up to four output clocks ranging from 8kHz up to 1.0GHz.

The PLL path within the 8T49N242 supports three states: Lock, Holdover and Free-run. Lock & holdover status may be monitored on register bits and pins. The PLL also supports automatic and manual hitless reference switching. In the locked state, the PLL locks to a valid clock input and its output clocks have a frequency accuracy equal to the frequency accuracy of the input clock. In the Holdover state, the PLL will output a clock which is based on the selected holdover behavior. The PLL within the 8T49N242 has an initial holdover frequency offset of ±50ppb. In the Free-run state, the PLL outputs a clock with the same frequency accuracy as the external crystal.

Upon power up, the PLL will enter Free-run state, in this state it generates output clocks with the same frequency accuracy as the external crystal. The 8T49N242 continuously monitors each input for activity (signal transitions). If no input references are provided, the device will remain locked to the crystal in Free-run state and will generate output frequencies as a synthesizer.

When an input clock has been validated the PLL will transition to the Lock state. In automatic reference switching, if the selected input clock fails and there are no other valid input clocks, the PLL will quickly detect that and go into Holdover. In the Holdover state, the PLL will output a clock which is based on the selected holdover behavior. If the selected input clock fails and another input clock is available then the 8T49N242 will hitlessly switch to that input clock. The reference switch can be either revertive or non-revertive. Manual switchover is also available with switchover only occurring on user command, either via register bit or via the Clock Select input function of the GPIO[3:0] pins.

The device supports conversion of any input frequencies to four different output frequencies: one independent output frequency on Q0 and three more integer-related frequencies on Q[1:3].

The 8T49N242 has a programmable loop bandwidth from 0.2Hz to 6.4kHz.

The device monitors all input clocks and generates an alarm when an input clock failure is detected.

The device is programmable through an I2C and may also autonomously read its register settings from an internal One-Time Programmable (OTP) memory or an external serial I2C EEPROM.

Crystal Input

The crystal input on the 8T49N242 is capable of being driven by a parallel-resonant, fundamental mode crystal with a frequency range of 10MHz – 50MHz.

The oscillator input also supports being driven by a single-ended crystal oscillator or reference clock.

The initial holdover frequency offset is set by the device, but the long term drift depends on the quality of the crystal or oscillator attached to this port.

This device provides the ability to double the crystal frequency input into the PLL for improved close-in phase noise performance. Refer to Figure 3.

Figure 3. Doubling Block Diagram

Bypass Path

The crystal input, CLK0 or CLK1 may be used directly as a clock source for the Q[2:3] output dividers. This may only be done for input frequencies of 250MHz or less.

Input Clock Selection

The 8T49N242 accepts up to two input clocks with frequencies ranging from 8kHz up to 875MHz. Each input can accept LVPECL, LVDS, LVHSTL, HCSL or LVCMOS inputs using 1.8V, 2.5V or 3.3V logic levels.

In Manual mode, only one of the inputs may be chosen and if that input fails that PLL will enter holdover.

Manual mode may be operated by directly selecting the desired input reference in the REFSEL register field. It may also operate via pin-selection of the desired input clock by selecting that mode in the REFSEL register field. In that case, GPIO[2] must be used as a Clock Select input (CSEL). CSEL = 0 will select the CLK0 input and CSEL = 1 will select the CLK1 input.

In addition, the crystal frequency may be passed directly to the output dividers Q[2:3] for use as a reference.
Inputs do not support transmission of spread-spectrum clocking sources. Since this family is intended for high-performance applications, it will assume input reference sources to have stabilities of ±100ppm or better, except where gapped clock inputs are used.

If the PLL is working in automatic mode, then one of the input reference sources is assigned as the higher priority. At power-up or if the currently selected input reference fails, the PLL will switch to the highest priority input reference that is valid at that time (see Input Clock Monitor for details).

Automatic mode has two sub-options: revertive or non-revertive. In revertive mode, the PLL will switch to a reference with a higher priority setting whenever one becomes valid. In non-revertive mode the PLL remains with the currently selected source as long as it remains valid.

The clock input selection is based on the input clock priority set by the Clock Input Priority control bit.

**Input Clock Monitor**

Each clock input is monitored for Loss of Signal (LOS). If no activity has been detected on the clock input within a user-selectable time period then the clock input is considered to be failed and an internal Loss-of-Signal status flag is set, which may cause an input switchover depending on other settings. The user-selectable time period has sufficient range to allow a gapped clock missing many consecutive edges to be considered a valid input.

User-selection of the clock monitor time-period is based on a counter driven by a monitor clock. The monitor clock is fixed at the frequency of the PLL’s VCO divided by 8. With a VCO range of 3GHz - 4GHz, the monitor clock has a frequency range of 375MHz to 500MHz.

The monitor logic for each input reference will count the number of monitor clock edges indicated in the appropriate Monitor Control register. If an edge is received on the input reference being monitored, then the count resets and begins again. If the target edge count is reached before an input reference edge is received, then an internal soft alarm is raised and the count re-starts. During the soft alarm period, the PLL tracking will not be adjusted. If an input reference edge is received before the count expires for the second time, then the soft alarm status is cleared and the PLL will resume adjustments. If the count expires again without any input reference edge being received, then a Loss-of-Signal alarm is declared.

It is expected that for normal (non-gapped) clock operation, users will set the monitor clock count for each input reference to be slightly longer than the nominal period of that input reference. A margin of 2-3 monitor clock periods should give a reasonably quick reaction time and yet prevent false alarms.

For gapped clock operation, the user will set the monitor clock count to a few monitor clock periods longer than the longest expected clock gap period. The monitor count registers support 17-bit count values, which will support at least a gap length of two clock periods for any supported input reference frequency, with longer gaps being supported for faster input reference frequencies.

Using this configuration for a gapped clock, the PLL will continue to adjust while the normally expected gap is present, but will freeze once the expected gap length has been exceeded and alarm after twice the normal gap length has passed.

Once a LOS on any of the input clocks is detected, the appropriate internal LOS alarm will be asserted and it will remain asserted until that input clock returns and is validated. Validation occurs once 8 rising edges have been received on that input reference. If another error condition on the same input clock is detected during the validation time then the alarm remains asserted and the validation period starts over.

Each LOS flag may also be reflected on one of the GPIO[3:0] outputs. Changes in status of any reference can also generate an interrupt if not masked.

**Holdover**

The 8T49N242 supports a small initial holdover frequency offset in non-gapped clock mode. When the input clock monitor is set to support gapped clock operation, this initial holdover frequency offset is indeterminate since the desired behavior with gapped clocks is for the PLL to continue to adjust itself even if clock edges are missing. In gapped clock mode, the PLL will not enter holdover until the input is missing for two LOS monitor periods.

The holdover performance characteristics of a clock are referred as its accuracy and stability, and are characterized in terms of the fractional frequency offset. The 8T49N242 can only control the initial frequency accuracy. Longer-term accuracy and stability are determined by the accuracy and stability of the external oscillator.

When the PLL loses all valid input references, it will enter the holdover state. In fast average mode, the PLL will initially maintain its most recent frequency offset setting and then transition at a rate dictated by its selected phase-slope limit setting to a frequency offset setting that is based on historical settings. This behavior is intended to compensate for any frequency drift that may have occurred on the input reference before it was detected to be lost.

The historical holdover value will have three options:

- Return to center of tuning range within the VCO band
- Instantaneous mode - the holdover frequency will use the DPLL current frequency 100msec before it entered holdover. The accuracy is shown in the AC Characteristics Table, Table 11.
- Fast average mode - an internal IIR (Infinite Impulse Response) filter is employed to get the frequency offset. The IIR filter gives a 3dB attenuation point corresponding to nominal a period of 20 minutes. The accuracy is shown in the AC Characteristics Table, Table 11.
When entering holdover, the PLL will set a separate internal HOLD alarm internally. This alarm may be read from internal status register, appear on the appropriate GPIO pin and/or assert the nINT output. While the PLL is in holdover, its frequency offset is now relative to the crystal input and so the output clocks will be tracing their accuracy to the local oscillator or crystal. At some point in time, depending on the stability & accuracy of that source, the clock(s) will have drifted outside of the limits of the holdover state and be considered to be in a free-run state. Since this borderline is defined outside the PLL and dictated by the accuracy and stability of the external local crystal or oscillator, the 8T49N242 cannot know or influence when that transition occurs.

Input to Output Clock Frequency
The 8T49N242 is designed to accept any frequency within its input range and generate four different output frequencies that are integer-related to the PLL frequency and hence to each other, but not to the input frequencies. The internal architecture of the device ensures that most translations will result in the exact output frequency specified. Please contact IDT for configuration software or other assistance in determining if a desired configuration will be supported exactly.

Synthesizer Mode Operation
The device may act as a frequency synthesizer with the PLL generating its operating frequency from just the crystal input. By setting the SYN_MODE register bit and setting the STATE[1:0] field to Freerun, no input clock references are required to generate the desired output frequencies.

When operating as a synthesizer, the precision of the output frequency will be < 1ppb for any supported configuration.

Loop Filter and Bandwidth
The 8T49N242 uses one external capacitor of fixed value to support its loop bandwidth. When operating in Synthesizer mode a fixed loop bandwidth of approximately 200kHz is provided. When not operating as a synthesizer, the 8T49N242 will support a range of loop bandwidths: 0.2Hz, 0.4Hz, 0.8Hz, 1.6Hz, 3.2Hz, 6.4Hz, 12Hz, 25Hz, 50Hz, 100Hz, 200Hz, 400Hz, 800Hz, 1.6kHz or 6.4kHz.

The device supports two different loop bandwidth settings: acquisition and locked. These loop bandwidths are selected from the list of options described above. If enabled, the acquisition bandwidth is used while lock is being acquired to allow the PLL to “fast-lock”. Once locked the PLL will use the locked bandwidth setting. If the acquisition bandwidth setting is not used, the PLL will use the locked bandwidth setting at all times.

Output Dividers
The 8T49N242 supports four integer output dividers. Each integer output divider block consists of two divider stages in a series to achieve the desired total output divider ratio. The first stage divider may be set to divide by 4, 5 or 6. In addition, the Q[2:3] first stage dividers may be bypassed if CLK0, CLK1 or the crystal are used as the clock source for them. The second stage of the divider may be bypassed (i.e. divide-by-1) or programmed to any even divider ratio from 2 to 131,070. The total divide ratios, settings and possible output frequencies are shown in Table 3.

An output synchronization via the PLL_SYN bit is necessary after programming the output dividers to ensure that the outputs are synchronized.

</table>
Output Divider Frequency Sources

Output dividers associated with the Q[0:1] outputs take their input frequency directly from the PLL.

Output dividers associated with the Q[2:3] outputs can take their input frequencies from the PLL, CLK0 or CLK1 input reference frequency or the crystal frequency.

Output Phase Control on Switchover

There are two options on how the output phase can be controlled when the 8T49N242 enters or leaves the holdover state, or the PLL switches between input references. Phase-slope limiting or fully hitless switching (sometimes called phase build-out) may be selected. The SWMODE bit selects which behavior is to be followed.

If fully hitless switching is selected, then the output phase will remain unchanged under any of these conditions. Note that fully hitless switching is not supported when external loopback is being used. Fully hitless switching should not be used unless all input references are in the same clock domain. Note that use of this mode may prevent an output frequency and phase from being able to trace its alignment back to a primary reference source.

If phase-slope limiting is selected, then the output phase will adjust from its previous value until it is tracking the new condition at a rate dictated by the SLEW[1:0] bits. Phase-slope limiting should be used if all input references are not in the same clock domain or users wish to retain traceability to a primary reference source.

Output Drivers

The Q0 to Q3 clock outputs are provided with register-controlled output drivers. By selecting the output drive type in the appropriate register, any of these outputs can support LVCMOS, LVPECL, HCSL or LVDS logic levels.

The operating voltage ranges of each output is determined by its independent output power pin (V_{CCO}) and thus each can have different output voltage levels. Output voltage levels of 2.5V or 3.3V are supported for differential operation and LVCMOS operation. In addition, LVCMOS output operation supports 1.8V V_{CCO}.

Each output may be enabled or disabled by register bits and/or GPIO pins.

LVCMOS Operation

When a given output is configured to provide LVCMOS levels, then both the Q and nQ outputs will toggle at the selected output frequency. All the previously described configuration and control apply equally to both outputs. Frequency, voltage levels and enable / disable status apply to both the Q and nQ pins. When configured as LVCMOS, the Q & nQ outputs can be selected to be phase-aligned with each other or inverted relative to one another. Selection of phase-alignment may have negative effects on the phase noise performance of any part of the device due to increased simultaneous switching noise within the device.

Power-Saving Modes

To allow the device to consume the least power possible for a given application, the following functions can be disabled via register programming:

- Any unused output, including all output divider logic, can be individually powered-off.
- Any unused input, including the clock monitoring logic can be individually powered-off.
- The digital PLL can be powered-off when running in synthesizer mode.
- Clock gating on logic that is not being used.

Status / Control Signals and Interrupts

The status and control signals for the device, may be operated at 1.8V, 2.5V or 3.3V as determined by the voltage applied to the V_{CCS} pins. All signals will share the same voltage levels.

Signals involved include: nWP, nINT, nRST, GPIO[3:0], S_A0, S_A1, SCLK and SDATA. The voltage used here is independent of the voltage chosen for the digital and analog core voltages and the output voltages selected for the clock outputs.
General-Purpose I/Os & Interrupts

The 8T49N242 provides four General Purpose Input / Output (GPIO) pins for miscellaneous status & control functions. Each GPIO may be configured as either an input or an output. Each GPIO may be directly controlled from register bits or be used as a predefined function as shown in Table 4. Note that the default state prior to configuration being loaded from internal OTP will be to set each GPIO to input direction to function as an Output Enable.

Table 4. GPIO Configuration

<table>
<thead>
<tr>
<th>GPIO Pin</th>
<th>Configured as Input</th>
<th>Configured as Output</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Fixed Function (default)</td>
<td>General Purpose</td>
</tr>
<tr>
<td>0</td>
<td>OSEL[0]</td>
<td>GPI[0]</td>
</tr>
</tbody>
</table>

NOTE 1:
GPI[x]: General Purpose Input. Logic state on GPIO[x] pin is directly reflected in GPI[x] register.
LOL: Loss-of-Lock Status Flag for Digital PLL. Logic-high indicates digital PLL not locked.
GPO[x]: General Purpose Output. Logic state is determined by value written in register GPO[x].
OSEL[n]: Output Enable Control Signals for Outputs Qx, nQx. Refer to Output Enable Operation section.
LOS[x]: Loss-of-Signal Status Flag for Input Reference x. Logic-high indicates input reference failure.
CSEL: Manual Clock Select Input for PLL. Logic-high selects differential clock input 1 (CLK1).
HOLD: Holdover Status Flag for Digital PLL. Logic-high indicates digital PLL in holdover status.
Refer to Register Descriptions for additional details.

If used in the Fixed Function mode of operation, the GPIO bits will reflect the real-time status of their respective status bits as shown in Table 4.

The LOL alarm will support two modes of operation:
• De-asserts once PLL is locked, or
• De-asserts after PLL is locked and all internal synchronization operations that may destabilize output clocks are completed.

Interrupt Functionality

Interrupt functionality includes an interrupt status flag for each of PLL Loss-of-Lock status (LOL), PLL in holdover status (HOLD) and Loss-of-Signal status for each input (LOS[1:0]). Those Status Flags are set whenever there is an alarm on their respective functions. The Status Flag will remain set until the alarm has been cleared and a ‘1’ has been written to the Status Flag’s register location or if a reset occurs. Each Status Flag will also have an Interrupt Enable bit that will determine if that Status Flag is allowed to cause the Device Interrupt Status to be affected (enabled) or not (disabled). All Interrupt Enable bits will be in the disabled state after reset. The Device Interrupt Status Flag and nINT output pin are asserted if any of the enabled interrupt Status Flags are set.

Output Enable Operation

When GPIO[1:0] are used as Output Enable control signals, the function of the pins is to select one of four register-based maps that indicate which outputs should be enabled or disabled.

Device Hardware Configuration

The 8T49N242 supports an internal One-Time Programmable (OTP) memory that can be pre-programmed at the factory with one complete device configuration. Some or all of this pre-programmed configuration will be loaded into the device’s registers on power-up or reset.

These default register settings can be over-written using the serial programming interface once reset is complete. Any configuration written via the serial programming interface needs to be re-written after any power cycle or reset. Please contact IDT if a specific factory-programmed configuration is desired.
Device Start-up and Reset Behavior

The 8T49N242 has an internal power-up reset (POR) circuit and a Master Reset input pin nRST. If either is asserted, the device will be in the Reset State.

For highly programmable devices, it is common practice to reset the device immediately after the initial power-on sequence. IDT recommends connecting the nRST input pin to a programmable logic source for optimal functionality. It is recommended that a minimum pulse width of 10ns be used to drive the nRST input.

While in the reset state (nRST input asserted or POR active), the device will operate as follows:

• All registers will return to & be held in their default states as indicated in the applicable register description.
• All internal state machines will be in their reset conditions.
• The serial interface will not respond to read or write cycles.
• The GPIO signals will be configured as Output Enable inputs.
• All clock outputs will be disabled.
• All interrupt status and Interrupt Enable bits will be cleared, negating the nINT signal.

Upon the later of the internal POR circuit expiring or the nRST input negating, the device will exit reset and begin self-configuration.

The device will load an initial block of its internal registers using the configuration stored in the internal One-Time Programmable (OTP) memory. Once this step is complete, the 8T49N242 will check the register settings to see if it should load the remainder of its configuration from an external I²C EEPROM on the I²C bus, Writing of the configuration to the serial EEPROM must be performed by another device on the same I²C bus or pre-programmed into the device prior to assembly.

Serial Control Port Description

Serial Control Port Configuration Description

The device has a serial control port capable of responding as a slave in an I²C compatible configuration, to allow access to any of the internal registers for device programming or examination of internal status. All registers are configured to have default values. See the specifics for each register for details.

The device has the additional capability of becoming a master on the I²C bus only for the purpose of reading its initial register configurations from a serial EEPROM on the I²C bus. Writing of the configuration to the serial EEPROM must be performed by another device on the same I²C bus or pre-programmed into the device prior to assembly.

I²C Mode Operation

The I²C interface is designed to fully support v2.1 of the I²C Specification for Normal and Fast mode operation. The device acts as a slave device on the I²C bus at 100kHz or 400kHz using the address defined in the Serial Interface Control register (0006h), as modified by the S_A0 & S_A1 input pin settings. The interface accepts byte-oriented block write and block read operations. Two address bytes specify the register address of the byte position of the first register to write or read. Data bytes (registers) are accessed in sequential order from the lowest to the highest byte (most significant bit first). Read and write block transfers can be stopped after any complete byte transfer. During a write operation, data will not be moved into the registers until the STOP bit is received, at which point, all data received in the block write will be written simultaneously.

For full electrical I²C compliance, it is recommended to use external pull-up resistors for SDATA and SCLK. The internal pull-up resistors have a size of 51kΩ typical.

Figure 5. I²C Slave Read and Write Cycle Sequencing
**I²C Master Mode**

When operating in I²C mode, the 8T49N242 has the capability to become a bus master on the I²C bus for the purposes of reading its configuration from an external I²C EEPROM. Only a block read cycle will be supported.

As an I²C bus master, the 8T49N242 will support the following functions:

- 7-bit addressing mode
- Base address register for EEPROM
- Validation of the read block via CCITT-8 CRC check against value stored in last byte (84h) of EEPROM
- Support for 100kHz and 400kHz operation with speed negotiation. If bit d0 is set at Byte address 05h in the EEPROM, this will shift from 100kHz operation to 400kHz operation.
- Support for 1- or 2-byte addressing mode
- Master arbitration with programmable number of retries
- Fixed-period cycle response timer to prevent permanently hanging the I²C bus.
- Read will abort with an alarm (BOOTFAIL) if any of the following conditions occur: Slave NACK, Arbitration Fail, Collision during Address Phase, CRC failure, Slave Response time-out

The 8T49N242 will not support the following functions:

- I²C General Call
- Slave clock stretching
- I²C Start Byte protocol
- EEPROM Chaining
- CBUS compatibility
- Responding to its own slave address when acting as a master
- Writing to external I²C devices including the external EEPROM used for booting

Figure 6. I²C Master Read Cycle Sequencing
I²C Boot-up Initialization Mode

If enabled (via the BOOT_EEP bit in the Startup register), once the nRST input has been de-asserted (high) and its internal power-up reset sequence has completed, the device will contend for ownership of the I²C bus to read its initial register settings from a memory location on the I²C bus. The address of that memory location is kept in non-volatile memory in the Startup register. During the boot-up process, the device will not respond to serial control port accesses. Once the initialization process is complete, the contents of any of the device’s registers can be altered. It is the responsibility of the user to make any desired adjustments in initial values directly in the serial bus memory.

If a NACK is received to any of the read cycles performed by the device during the initialization process, or if the CRC does not match the one stored in address 84h of the EEPROM the process will be aborted and any uninitialized registers will remain with their default values. The BOOTFAIL bit in the Global Interrupt Status register (0210h) will also be set in this event.

Contents of the EEPROM should be as shown in Table 5.

Table 7O. Interrupt Status Register Bit Field Locations and Descriptions

This register contains “sticky” bits for tracking the status of the various alarms. Whenever an alarm occurs, the appropriate Interrupt Status bit will be set. The Interrupt Status bit will remain asserted even after the original alarm goes away. The Interrupt Status bits remain asserted until explicitly cleared by a write of a ‘1’ to the bit over the serial port. This type of functionality is referred to as Read / Write-1-to-Clear (R/W1C).

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the DC Characteristics or AC Characteristics is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

NOTE 1: $V_{CCOX}$ denotes $V_{CCO0}$, $V_{CCO1}$, $V_{CCO2}$, $V_{CCO3}$.

NOTE 2: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lpfm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

NOTE 3: Appropriate SE_MODE bit must be configured to select phase-aligned or phase-inverted operation.

NOTE 4: All Q and nQ outputs in phase-inverted operation.

NOTE 5: This parameter is guaranteed by characterization. Not tested in production.

NOTE 6: This parameter is defined in accordance with JEDEC Standard 65.

NOTE 7: Measured at the output differential cross point.
NOTE 8: Defined as skew within a bank of outputs at the same supply voltage and with equal load conditions.
NOTE 9: Measured at $V_{CCOx}/2$ of the rising edge. All Qx and nQx outputs phase-aligned.
NOTE 10: Characterized in PLL Mode. Duty cycle of bypassed signals (input reference clocks or crystal input) is not adjusted by the device.
NOTE 11: This parameter was measured using CLK0 as the reference input and CLK1 as the external feedback input. Characterized with 8T49N242-902.
NOTE 12: Tested in fast-lock operation after >20 minutes of locked operation to ensure holdover averaging logic is stable.
NOTE 13: This parameter is guaranteed by design.
NOTE 14: Using internal feedback mode configuration.
NOTE 15: Device programmed with SWMODE = 0 (absorbs phase differences).
NOTE 16: Characterized with 8T49N242-900.
NOTE 17: Tested with all outputs operating at 122.88MHz.
NOTE 18: Assuming a clear I²C bus.
Table 12. HCSL AC Characteristics, $V_{CC} = 3.3V \pm 5\%$ or $2.5V \pm 5\%$, $V_{CCOX} = 3.3V \pm 5\%$ or $2.5V \pm 5\%$, $T_A = -40^\circ C$ to $85^\circ C$\(^1\),\(^2\)

NOTE 1: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lpm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

NOTE 2: $V_{CCOX}$ denotes $V_{CCO0}$, $V_{CCO1}$, $V_{CCO2}$, $V_{CCO3}$.

NOTE 3: Measurement taken from differential waveform.

NOTE 4: $t_{STABLE}$ is the time the differential clock must maintain a minimum $\pm 150$ mV differential voltage after rising/falling edges before it is allowed to drop back into the $V_{RB}$ $\pm 100$ mV differential range.

NOTE 5: Measurement taken from single ended waveform.

NOTE 6: Defined as the maximum instantaneous voltage including overshoot.

NOTE 7: Defined as the minimum instantaneous voltage including undershoot.

NOTE 8: Measured at crossing point where the instantaneous voltage value of the rising edge of Qx equals the falling edge of nQx.

NOTE 9: Refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing. Refers to all crossing points for this measurement.

NOTE 10: Defined as the total variation of all crossing voltages of rising Qx and falling nQx, This is the maximum allowed variance in $V_{CROSS}$ for any particular system.

Noise Power (dBc)

Offset Frequency (Hz)
Applications Information

Recommendations for Unused Input and Output Pins

Inputs:

CLKx/nCLKx Input
For applications not requiring the use of one or more reference clock inputs, both CLKx and nCLKx can be left floating. Though not required, but for additional protection, a 1kΩ resistor can be tied from CLKx to ground. It is recommended that CLKx, nCLKx not be driven with active signals when not selected.

LVCMOS Control Pins
All control pins have internal pullups or pulldowns; additional resistance is not required but can be added for additional protection. A 1kΩ resistor can be used.

Outputs:

LVPECL Outputs
Any unused LVPECL output pair can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.

LVDS Outputs
Any unused LVDS output pair can be either left floating or terminated with 100Ω across. If they are left floating there should be no trace attached.

LVCMOS Outputs
Any LVCMOS output can be left floating if unused. There should be no trace attached.

HCSL Outputs
All unused differential outputs can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.
Overdriving the XTAL Interface

The OSCI input can be overdriven by an LVCMOS driver or by one side of a differential driver through an AC coupling capacitor. The OSCO pin can be left floating. The amplitude of the input signal should be between 500mV and 1.8V and the slew rate should not be less than 0.2V/μS. For 3.3V LVCMOS inputs, the amplitude must be reduced from full swing to at least half the swing in order to prevent signal interference with the power rail and to reduce internal noise. Figure 7A shows an example of the interface diagram for a high speed 3.3V LVCMOS driver. This configuration requires that the sum of the output impedance of the driver (Ro) and the series resistance (Rs) equals the transmission line impedance. In addition, matched termination at the crystal input will attenuate the signal in half. This can be done in one of two ways. First, R1 and R2 in parallel should equal the transmission line impedance. For most 50Ω applications, R1 and R2 can be 100Ω. This can also be accomplished by removing R1 and changing R2 to 50Ω. The values of the resistors can be increased to reduce the loading for a slower and weaker LVCMOS driver. Figure 7B shows an example of the interface diagram for an LVPECL driver. This is a standard LVPECL termination with one side of the driver feeding the OSCI input. It is recommended that all components in the schematics be placed in the layout. Though some components might not be used, they can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a quartz crystal as the input.
Wiring the Differential Input to Accept Single-Ended Levels

Figure 8 shows how a differential input can be wired to accept single ended levels. The reference voltage \( V_{\text{REF}} = V_{\text{CC}}/2 \) is generated by the bias resistors R1 and R2. The bypass capacitor (C1) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of R1 and R2 might need to be adjusted to position the \( V_{\text{REF}} \) in the center of the input voltage swing. For example, if the input clock swing is 2.5V and \( V_{\text{CC}} = 3.3V \), R1 and R2 value should be adjusted to set \( V_{\text{REF}} \) at 1.25V. The values below are for when both the single ended swing and \( V_{\text{CC}} \) are at the same voltage. This configuration requires that the sum of the output impedance of the driver (\( R_o \)) and the series resistance (\( R_s \)) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First, R3 and R4 in parallel should equal the transmission line impedance. For most 50Ω applications, R3 and R4 can be 100Ω.

The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver. When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVCMOS signaling, it is recommended that the amplitude be reduced. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however \( V_{\text{IL}} \) cannot be less than -0.3V and \( V_{\text{IH}} \) cannot be more than \( V_{\text{CC}} + 0.3V \). Suggest edge rate faster than 1V/ns. Though some of the recommended components might not be used, the pads should be placed in the layout. They can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

![Figure 8. Recommended Schematic for Wiring a Differential Input to Accept Single-ended Levels](image-url)
3.3V Differential Clock Input Interface

CLKx/nCLKx accepts LVDS, LVPECL, LVHSTL, HCSL and other differential signals. Both $V_{SWING}$ and $V_{OH}$ must meet the $V_{PP}$ and $V_{CMR}$ input requirements. Figures 9A to 9E show interface examples for the CLKx/nCLKx input driven by the most common driver types. The input interfaces suggested here are examples only.

Please consult with the vendor of the driver component to confirm the driver termination requirements. For example, in Figure 9A, the input termination applies for IDT open emitter LVHSTL drivers. If you are using an LVHSTL driver from another vendor, use their termination recommendation.

**LVDS Driver Termination**

For a general LVDS interface, the recommended value for the termination impedance ($Z_T$) is between $90\,\Omega$ and $132\,\Omega$. The actual value should be selected to match the differential impedance ($Z_0$) of your transmission line. A typical point-to-point LVDS design uses a $100\,\Omega$ parallel resistor at the receiver and a $100\,\Omega$ differential transmission-line environment. In order to avoid any transmission-line reflection issues, the components should be surface mounted and must be placed as close to the receiver as possible. IDT offers a full line of LVDS compliant devices with two types of output structures: current source and voltage source. The standard termination schematic as shown in *Figure 11A* can be used with either type of output structure. *Figure 11B*, which can also be used with both output types, is an optional termination with center tap capacitance to help filter common mode noise. The capacitor value should be approximately $50\,\text{pF}$. If using a non-standard termination, it is recommended to contact IDT and confirm if the output structure is current source or voltage source type. In addition, since these outputs are LVDS compatible, the input receiver’s amplitude and common-mode input range should be verified for compatibility with the output.

![Figure 11A. Standard LVDS Termination](image)

![Figure 11B. Optional LVDS Termination](image)
Termination for 3.3V LVPECL Outputs

The clock layout topology shown below is a typical termination for LVPECL outputs. The two different layouts mentioned are recommended only as guidelines.

The differential outputs generate ECL/LVPECL compatible outputs. Therefore, terminating resistors (DC current path to ground) or current sources must be used for functionality. These outputs are designed to drive 50Ω transmission lines. Matched impedance techniques should be used to maximize operating frequency and minimize signal distortion. Figure 12A and Figure 12B show two different layouts which are recommended only as guidelines. Other suitable clock layouts may exist and it would be recommended that the board designers simulate to guarantee compatibility across all printed circuit and clock component process variations.

![Figure 12A. 3.3V LVPECL Output Termination](image)

![Figure 12B. 3.3V LVPECL Output Termination](image)
Termination for 2.5V LVPECL Outputs

Figure 13A and Figure 13C show examples of termination for 2.5V LVPECL driver. These terminations are equivalent to terminating 50Ω to $V_{CCO} - 2V$. For $V_{CCO} = 2.5V$, the $V_{CCO} - 2V$ is very close to ground level. The R3 in Figure 13C can be eliminated and the termination is shown in Figure 13B.
HCSL Recommended Termination

*Figure 14A* is the recommended source termination for applications where the driver and receiver will be on separate PCBs. This termination is the standard for PCI Express™ and HCSL output types. All traces should be 50Ω impedance single-ended or 100Ω differential.

---

**Figure 14A. Recommended Source Termination (where the driver and receiver will be on separate PCBs)**

*Figure 14A* is the recommended termination for applications where a point-to-point connection can be used. A point-to-point connection contains both the driver and the receiver on the same PCB. With a matched termination at the receiver, transmission-line reflections will be minimized. In addition, a series resistor (Rs) at the driver offers flexibility and can help dampen unwanted reflections. The optional resistor can range from 0Ω to 33Ω. All traces should be 50Ω impedance single-ended or 100Ω differential.

---

**Figure 14B. Recommended Termination (where a point-to-point connection can be used)**
VFQFPN EPAD Thermal Release Path

In order to maximize both the removal of heat from the package and the electrical performance, a land pattern must be incorporated on the Printed Circuit Board (PCB) within the footprint of the package corresponding to the exposed metal pad or exposed heat slug on the package, as shown in Figure 15. The solderable area on the PCB, as defined by the solder mask, should be at least the same size/shape as the exposed pad/slug area on the package to maximize the thermal/electrical performance. Sufficient clearance should be designed on the PCB between the outer edges of the land pattern and the inner edges of pad pattern for the leads to avoid any shorts.

While the land pattern on the PCB provides a means of heat transfer and electrical grounding from the package to the board through a solder joint, thermal vias are necessary to effectively conduct from the surface of the PCB to the ground plane(s). The land pattern must be connected to ground through these vias. The vias act as “heat pipes”. The number of vias (i.e. “heat pipes”) are application specific and dependent upon the package power dissipation as well as electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. Maximum thermal and electrical performance is achieved when an array of vias is incorporated in the land pattern. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13mil (0.30 to 0.33mm) with 1oz copper via barrel plating. This is desirable to avoid any solder wicking inside the via during the soldering process which may result in voids in solder between the exposed pad/slug and the thermal land. Precautions should be taken to eliminate any solder voids between the exposed heat slug and the land pattern. Note: These recommendations are to be used as a guideline only. For further information, please refer to the Application Note on the Surface Mount Assembly of Amkor’s Thermally/Electrically Enhance Lead frame Base Package, Amkor Technology.

Figure 15. P.C. Assembly for Exposed Pad Thermal Release Path – Side View (drawing not to scale)

Schematic and Layout Information

Schematics for the 8T49N242 can be found on IDT.com. Please search for the 8T49N242 and click on the link for evaluation board. The evaluation board user guide includes schematic and layout information.

Crystal Recommendation

This device was validated using FOX 277LF series through-hole crystals including Part # 277LF-40-18 (40MHz). If a surface mount crystal is desired, we recommend IDT Part # 603-40-48 (40MHz) and FOX Part #603-40-48 (40MHz).
PCI Express Application Note

PCI Express jitter analysis methodology models the system response to reference clock jitter. The block diagram below shows the most frequently used Common Clock Architecture in which a copy of the reference clock is provided to both ends of the PCI Express Link.

In the jitter analysis, the transmit (Tx) and receive (Rx) SerDes PLLs are modeled as well as the phase interpolator in the receiver. These transfer functions are called H1, H2, and H3 respectively. The overall system transfer function at the receiver is:

\[ H_t(s) = H_3(s) \times [H_1(s) - H_2(s)] \]

The jitter spectrum seen by the receiver is the result of applying this system transfer function to the clock spectrum \( X(s) \) and is:

\[ Y(s) = X(s) \times H_3(s) \times [H_1(s) - H_2(s)] \]

In order to generate time domain jitter numbers, an inverse Fourier Transform is performed on \( X(s) \times H_3(s) \times [H_1(s) - H_2(s)] \).

PCI Express Common Clock Architecture

For PCI Express Gen 1, one transfer function is defined and the evaluation is performed over the entire spectrum: DC to Nyquist (e.g. for a 100MHz reference clock: 0Hz – 50MHz) and the jitter result is reported in peak-peak.

For PCI Express Gen 2, two transfer functions are defined with 2 evaluation ranges and the final jitter number is reported in RMS. The two evaluation ranges for PCI Express Gen 2 are 10kHz – 1.5MHz (Low Band) and 1.5MHz – Nyquist (High Band). The plots show the individual transfer functions as well as the overall transfer function \( H_t \).

For PCI Express Gen 3, one transfer function is defined and the evaluation is performed over the entire spectrum. The transfer function parameters are different from Gen 1 and the jitter result is reported in RMS.

For a more thorough overview of PCI Express jitter analysis methodology, please refer to IDT Application Note PCI Express Reference Clock Requirements.
Power Dissipation and Thermal Considerations

The 8T49N242 is a multi-functional, high speed device that targets a wide variety of clock frequencies and applications. Since this device is highly programmable with a broad range of features and functionality, the power consumption will vary as these features and functions are enabled.

The 8T49N242 is designed and characterized to operate within the ambient industrial temperature range of -40°C to 85°C. The ambient temperature represents the temperature around the device, not the junction temperature. When using the device in extreme cases, such as maximum operating frequency and high ambient temperature, external air flow may be required in order to ensure a safe and reliable junction temperature. Extreme care must be taken to avoid exceeding 125°C junction temperature.

The power calculation examples below are generated using maximum ambient temperature and supply voltage. For many applications, the power consumption will be much lower. Please contact IDT technical support for any concerns on calculating the power dissipation for your own specific configuration.

Power Domains

The 8T49N242 has a number of separate power domains that can be independently enabled and disabled via register accesses (all power supply pins must still be connected to a valid supply voltage). Figure 16 below indicates the individual domains and the associated power pins.

```
CLK Input & Divider Block (Core VCC)
Analog & Digital PLL (VCCA & Core VCC)
Output Divider / Buffer Q0 (VCCO0)
Output Divider / Buffer Q1 (VCCO1)
Output Divider / Buffer Q2 (VCCO2)
Output Divider / Buffer Q3 (VCCO3)
```

Figure 16. 8T49N242 Power Domains

Power Consumption Calculation

Determining total power consumption involves several steps:

1. Determine the power consumption using maximum current values for core and analog voltage supplies from Table 8A and Table 8B.
2. Determine the nominal power consumption of each enabled output path which consists of:
   a. A base amount of power that is independent of operating frequency, as shown in Table 15A through Table 15I (depending on the chosen output protocol).
   b. A variable amount of power that is related to the output frequency. This can be determined by multiplying the output frequency by the FQ_Factor shown in Table 15A through Table 15I.
3. All of the above totals are summed.
Thermal Considerations

Once the total power consumption has been determined, it is necessary to calculate the maximum operating junction temperature for the device under the environmental conditions it will operate in. Thermal conduction paths, air flow rate and ambient air temperature are factors that can affect this. The thermal conduction path refers to whether heat is to be conducted away via a heatsink, via airflow or via conduction into the PCB through the device pads (including the ePAD). Thermal conduction data is provided for typical scenarios in Table 14 below. Please contact IDT for assistance in calculating results under other scenarios.

</table>

Applying the values to the following equation will yield output current by frequency:

\[ \text{Qx Current (mA)} = \text{FQ\_Factor} \times \text{Frequency (MHz)} + \text{Base\_Current} \]

where:

- \( \text{Qx Current} \) is the specific output current according to output type and frequency
- \( \text{FQ\_Factor} \) is used for calculating current increase due to output frequency
- \( \text{Base\_Current} \) is the base current for each output path independent of output frequency

The second step is to multiply the power dissipated by the thermal impedance to determine the maximum power gradient, using the following equation:

\[ T_J = T_A + (\theta_{JA} \times P_{d\_total}) \]

where:

- \( T_J \) is the junction temperature (°C)
- \( T_A \) is the ambient temperature (°C)
- \( \theta_{JA} \) is the thermal resistance value from Table 14, dependent on ambient airflow (°C/W)
- \( P_{d\_total} \) is the total power dissipation of the 8T49N242 under usage conditions, including power dissipated due to loading (W).

Note that the power dissipation per output pair due to loading is assumed to be 27.95mW for LVPECL outputs and 44.5mW for HCSL outputs. When selecting LVCMOS outputs, power dissipation through the load will vary based on a variety of factors including termination type and trace length. For these examples, power dissipation through loading will be calculated using \( C_{PD} \) (found in Table 2) and output frequency:

\[ P_{d\_OUT} = C_{PD} \times F_{OUT} \times V_{CCO}^2 \]

where:

- \( P_{d\_OUT} \) is the power dissipation of the output (W)
- \( C_{PD} \) is the power dissipation capacitance (pF)
- \( F_{OUT} \) is the output frequency of the selected output (MHz)
- \( V_{CCO} \) is the voltage supplied to the appropriate output (V)
Example Calculations

Example 1. Common Customer Configuration (3.3V Core Voltage)

<table>

</table>

- Core Supply Current + Control and Status Supply Current = \( I_{CC} + I_{CCS} = 52\text{mA (max)} \)
- Analog Supply Current, \( I_{CCA} = 119\text{mA (max)} \)
- Output Supply Current:
  - Q0 Current = 125 * 0.00682 + 33.3 = 34.15mA
  - Q1 Current = 100 * 0.00682 + 33.3 = 33.98mA
  - Q2 Current = 50 * 0.00682 + 33.3 = 33.64mA
  - Q3 Current = 25 * 0.00682 + 33.3 = 33.47mA
- Total Output Supply Current = \( 135.24\text{mA (max)} \)
- Total Device Current = 52mA + 119mA + 135.24mA = \( 306.24\text{mA} \)
- Total Device Power = 3.465V * 306.24mA = \( 1061.12\text{mW} \)
- Power dissipated through output loading:
  - LVPECL = 27.95mW * 4 = \( 111.8\text{mW} \)
  - LVDS = already accounted for in device power
  - HCSL = n/a
  - LVCMOS = n/a
- Total Power = 1061.12mW + 111.8mW = \( 1172.92\text{mW or 1.17W} \)

With an ambient temperature of 85°C and no airflow, the junction temperature is:

\[ T_J = 85°C + 26.3°C/\text{W} \times 1.17W = 115.8°C \]

This is below the limit of 125°C.

## Revision History

<table>
<thead>
<tr>
<th>Date</th>
<th>Description of Change</th>
</tr>
</thead>
</table>
| **January 16, 2019** | • Corrected the I2C read sequence diagrams in Figure 5 and Figure 6 to match I2C specification and device actual performance. Note: Only the drawings were incorrect – the part’s behavior did not change and continues to meet the I2C specification.  
• Added a Marking Diagram |
| **July 30, 2018** | Per PCN# N1807-01, effective date August 19, 2018  
Updated the package outline drawings; however, no technical changes |
| **January 31, 2018** | Updated I2C Mode Operation to indicate support for v2.1 of the I2C specification  
Changed all package references to QFN or VFQFN to VFQFPN  
Updated the package outline drawings; however, no technical changes |
| **October 10, 2017** | Fixed some minor typographical errors. No technical changes. |
| **August 3, 2017** | Added CXTAL symbol.  
Updated the package outline drawings – no technical differences. |
| **October 31, 2016** | Crystal Recommendation - deleted IDT crystal reference. |
| **September 9, 2016** | Register Blocks Table, changed 0202 - 020B row.  
Corrected register location in paragraph from 0x0219 to 0x020C.  
Analog PLL Control Register Descriptions Table, changed VCOMAN[2:0] row. |
| **February 26, 2016** | Features section - added additional information on use of external oscillator.  
Pin Description Table - updated pins 33, 34, 37, 38.  
Principles of Operation - Output Phase Control on Switchover - added sentence to second and third paragraphs.  
GPIO Configuration Table - added Note 1.  
Power Supply Table - Updated table notes.  
Power Supply Table - Updated table notes.  
Maximum Output Supply Current Table - updated table notes. |
| **August 7, 2015** | Miscellaneous content enhancement in: Table 6, row 0213 - 03FF (from 0213 - 3FF),  
Table 7Q, row 0212 (from 212); Table 13B, Test Conditions, corrected 25MHz to 40MHz;  
Table 16, updated note. |
| **July 21, 2015** | Device Start-up and Reset Behavior - added sentence to second paragraph. |
NOTES:
1. ALL DIMENSIONS ARE IN MM. ANGLES IN DEGREES
40-VFQFPN Package Outline Drawing
6.0 x 6.0 x 0.9 mm, 0.5mm Pitch, 4.65 x 4.65 mm Epad
