General Description

The IDT8V41N004I is a clock generator designed for Gigabit Ethernet, 10 Gigabit Ethernet, SGMII and PCI Express™ applications. The device generates a selectable 100MHz, 125MHz, 156.25MHz or 312.5MHz clock signal from 25MHz input. The IDT8V41N004I uses IDT’s fourth generation FemtoClock®NG technology to provide low phase noise performance, combined with excellent power supply noise rejection for optimal performance in the targeted applications. The device supports a 3.3V supply voltage and is packaged in a compact, lead-free (RoHS 6) 32-lead VFQFN package. The industrial temperature range supports high end computing, telecommunication and networking end equipment requirements.

Features

- Fourth generation FemtoClock® NG technology
- Four 100MHz, 125MHz, 156.25MHz and 312.5MHz clocks for Gigabit Ethernet, 10 Gigabit Ethernet, SGMII and PCI Express applications, HCSL interface levels
- Selectable external crystal or differential input source
- Crystal oscillator interface designed for 25MHz parallel resonant crystal
- Differential CLK, nCLK input pair accepts LVPECL, LVDS, LVHSTL, HCSL input levels
- Internal resistor bias on nCLK pin allows the user to drive CLK input with external single-ended (LVCMOS/ LVTTL) input levels
- PCI Express Gen1, Gen2, and Gen 3 compliant
- RMS phase jitter 156.25MHz (12kHz - 20MHz): 0.217ps
- Full 3.3V supply voltage
- -40°C to 85°C ambient operating temperature

## Table 1. Pin Descriptions

<table>
<thead>
<tr>
<th>Number</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1      | PLL_BYPASS      | Input    | Pulldown  
Active HIGH PLL bypass. LVCMOS/LVTTL interface levels.  
PLL_BYPASS = 0: PLL mode (default)  
PLL_BYPASS = 1: Bypass mode |
| 2      | OE_REF          | Input    | Pulldown  
Active HIGH output enable for REF_OUT, nREF_OUT differential output. LVCMOS/LVTTL interface levels.  
OE_REF = 0: Output REF_OUT disabled/high impedance (default)  
OE_REF = 1: Output REF_OUT enabled |
| 3      | OE1             | Input    | Pulldown  
Active HIGH output enable for Q1, nQ1 differential output. LVCMOS/LVTTL interface levels.  
OE1 = 0: Output Q1 disabled/high impedance (default)  
OE1 = 1: Output Q1 enabled |
| 4      | OE0             | Input    | Pulldown  
Active HIGH output enable for Q0, nQ0 differential output. LVCMOS/LVTTL interface levels.  
OE0 = 0: Output Q0 disabled/high impedance (default)  
OE0 = 1: Output Q0 enabled |
| 5      | IREF            | Input    | Pullup/Pulldown  
External fixed precision resistor (475Ω) from this pin to ground provides a reference current used for HCSL outputs. |
| 6, 14, 22, 28, 31 | V_DD   | Power    | Supply voltage pins. |
| 7      | CLK             | Input    | Pulldown  
Non-inverting differential clock input. |
| 8      | nCLK            | Input    | Pullup/Pulldown  
Inverting differential clock input. V_DD/2 default when left floating. |
| 9, 10  | REF_OUT, nREF_OUT | Output      | Differential reference clock output pair. HCSL interface levels. |
| 11     | CLK_SEL         | Input    | Pulldown  
Active HIGH clock select input. Selects PLL input source. LVCMOS/LVTTL interface levels.  
CLK_SEL = 0: XTL_IN, XTL_OUT (default)  
CLK_SEL = 1: CLK, nCLK |
| 12, 13 | XTL_IN, XTL_OUT | Input    | Crystal oscillator interface. XTL_IN is the input., XTL_OUT is the output. |
| 15, 16 | FSEL0, FSEL1    | Input    | Pulldown  
Output frequency select pins. LVCMOS/LVTTL interface levels.  
FSEL[1:0] = 00: FOOUT = 156.25MHz (default)  
FSEL[1:0] = 01: FOOUT = 100MHz  
FSEL[1:0] = 10: FOOUT = 125MHz  
FSEL[1:0] = 11: FOOUT = 312.5MHz |
| 17, 18 | nQ3, Q3         | Output   | Differential output pair. HCSL interface levels. |
| 19, 25 | GND             | Power    | Power supply ground. |
| 20, 21 | nQ2, Q2         | Output   | Differential output pair. HCSL interface levels. |
| 23, 24 | nQ1, Q1         | Output   | Differential output pair. HSCL interface levels. |
| 26, 27 | nQ0, Q0         | Output   | Differential output pair. HCSL interface levels. |
| 29     | OE3             | Input    | Pulldown  
Active HIGH output enable for Q3, nQ3 differential output. LVCMOS/LVTTL interface levels.  
OE3 = 0: Output Q3 disabled/high impedance (default)  
OE3 = 1: Output Q3 enabled |
| 30     | OE2             | Input    | Pulldown  
Active HIGH output enable for Q2, nQ2 differential output. LVCMOS/LVTTL interface levels.  
OE2 = 0: Output Q2 disabled/high impedance (default)  
OE2 = 1: Output Q2 enabled |
| 32     | V_DDA           | Power    | Analog supply voltage. |

**NOTE:** Pulldown and Pullup refer to internal input resistors. See Table 2, Pin Characteristics, for typical values.

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the DC Characteristics or AC Characteristics is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

**NOTE:** Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 fpm. The device will meet specifications after thermal equilibrium has been reached under these conditions. For additional information, refer to the **PCI Express Application Note section** in the datasheet.

**NOTE 1:** Peak-to-Peak jitter after applying system transfer function for the Common Clock Architecture. Maximum limit for PCI Express Gen 1 is 86ps peak-to-peak for a sample size of $10^6$ clock periods.

**NOTE 2:** RMS jitter after applying the two evaluation bands to the two transfer functions defined in the Common Clock Architecture and reporting the worst case results for each evaluation band. Maximum limit for PCI Express Generation 2 is 3.1ps RMS for $t_{REFCLK_HF_RMS}$ (High Band) and 3.0ps RMS for $t_{REFCLK_LF_RMS}$ (Low Band).

**NOTE 3:** RMS jitter after applying system transfer function for the common clock architecture. This specification is based on the **PCI Express Base Specification Revision 0.7, October 2009** and is subject to change pending the final release version of the specification.

**NOTE 4:** This parameter is guaranteed by characterization. Not tested in production.

### Electrical Parameters

- **$V_{CROSS}$**: Absolute Crossing Voltage; NOTE 5, 10, 11
  - $f_{OUT} = 100\text{MHz}$
  - **Units**: mV
  - **Minimum**: 230
  - **Typical**: 550
  
- **$\Delta V_{CROSS}$**: Total Variation of $V_{CROSS}$ Over all Edges; NOTE 5, 10, 12
  - **Units**: mV
  - **Maximum**: 140

- **PSNR**: Power Supply Noise Rejection
  - **Units**: dB
  - **Value**: 45

- **$t_{SLEW+}$**: Rising Edge Rate; NOTE 8, 13
  - **Units**: V/ns
  - **Value**: 0.6

- **$t_{SLEW-}$**: Falling Edge Rate; NOTE 8, 13
  - **Units**: V/ns
  - **Value**: 4.0

- **$odc$**: Output Duty Cycle; NOTE 8
  - **Parameter**: Q[0:3], nQ[0:3]; 25MHz Crystal Input
  - **Units**: %
  - **Value**: 45

### Notes

- **NOTE 1**: Refer to Phase Noise Plot section.
- **NOTE 2**: REF_OUT, nREF_OUT is disabled.
- **NOTE 3**: This parameter is defined in accordance with JEDEC Standard 65.
- **NOTE 4**: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at the output differential cross points.
- **NOTE 5**: Measurement taken from a single ended waveform.
- **NOTE 6**: Defined as the maximum instantaneous voltage including overshoot. See Parameter Measurement Information Section.
- **NOTE 7**: Defined as the minimum instantaneous voltage including undershoot. See Parameter Measurement Information Section.
- **NOTE 8**: Measurement taken from a differential waveform.
- **NOTE 9**: $T_{STABLE}$ is the time the differential clock must maintain a minimum $\pm 150\text{mV}$ differential voltage after rising/falling edges before it is allowed to drop back into the $V_{RB} \pm 100\text{mV}$ differential range.
- **NOTE 10**: Measured at crossing point where the instantaneous voltage value of the rising edge of Qx+ equals the falling edge of Qx-.
- **NOTE 11**: Refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing. Refers to all crossing points for this measurement.
- **NOTE 12**: Defined as the total variation of all crossing voltages of rising Qx+ and falling Qx-, This is the maximum allowed variance in Vcross for any particular system. See Parameter Measurement Information Section.
- **NOTE 13**: Measured from -150mV to +150mV on the differential waveform (derived from Q minus nQ). The signal must be monotonic through the measurement region for rise and fall time. The 300mV measurement window is centered on the differential zero crossing.

Applications Information

Recommendations for Unused Input and Output Pins

Inputs:

CLK/nCLK Inputs
For applications not requiring the use of the differential input, both CLK and nCLK can be left floating. Though not required, but for additional protection, a 1kΩ resistor can be tied from CLK to ground.

Crystal Inputs
For applications not requiring the use of the crystal oscillator input, both XTAL_IN and XTAL_OUT can be left floating. Though not required, but for additional protection, a 1kΩ resistor can be tied from XTAL_IN to ground.

LVCMOS Control Pins
All control pins have internal pulldowns; additional resistance is not required but can be added for additional protection. A 1kΩ resistor can be used.

Outputs:

Differential Outputs
All unused differential outputs can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.

Wiring the Differential Input to Accept Single-Ended Levels

Figure 1 shows how a differential input can be wired to accept single ended levels. The reference voltage $V_1 = V_{DD}/2$ is generated by the bias resistors R1 and R2. The bypass capacitor (C1) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of R1 and R2 might need to be adjusted to position the $V_1$ in the center of the input voltage swing. For example, if the input clock swing is 2.5V and $V_{DD} = 3.3V$, R1 and R2 value should be adjusted to set $V_1$ at 1.25V. The values below are for when both the single ended swing and $V_{DD}$ are at the same voltage. This configuration requires that the sum of the output impedance of the driver (Ro) and the series resistance (Rs) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First, R3 and R4 in parallel should equal the transmission line impedance. For most 50Ω applications, R3 and R4 can be 100Ω. The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver. When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVCMOS signaling, it is recommended that the amplitude be reduced. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however $V_{IL}$ cannot be less than -0.3V and $V_{IH}$ cannot be more than $V_{DD} + 0.3V$. Though some of the recommended components might not be used, the pads should be placed in the layout. They can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

Figure 1. Recommended Schematic for Wiring a Differential Input to Accept Single-ended Levels
Differential Clock Input Interface

The CLK / nCLK accepts LVDS, LVPECL, LVHSTL, HCSL and other differential signals. Both signals must meet the \( V_{\text{PP}} \) and \( V_{\text{CMR}} \) input requirements. Figures 2A to 2E show interface examples for the CLK/nCLK input driven by the most common driver types. The input interfaces suggested here are examples only. Please consult with the vendor of the driver component to confirm the driver termination requirements. For example, in Figure 2A, the input termination applies for IDT open emitter LVHSTL drivers. If you are using an LVHSTL driver from another vendor, use their termination recommendation.

**Figure 2A.** CLK/nCLK Input Driven by an IDT Open Emitter LVHSTL Driver

**Figure 2B.** CLK/nCLK Input Driven by a 3.3V LVPECL Driver

**Figure 2C.** CLK/nCLK Input Driven by a 3.3V LVPECL Driver

**Figure 2D.** CLK/nCLK Input Driven by a 3.3V LVDS Driver

**Figure 2E.** CLK/nCLK Input Driven by a 3.3V HCSL Driver

*Optional – R3 and R4 can be 0Ω*
Power Supply Sequence Requirement

The IDT8V41N004I has a power supply sequence requirement. This device requires that \( V_{DD} \) and \( V_{DDA} \) are powered simultaneously. This device has been characterized using the recommended power supply filtering techniques in Figure 4.

Overdriving the XTAL Interface

The XTAL_IN input can be overdriven by an LVCMOS driver or by one side of a differential driver through an AC coupling capacitor. The XTAL_OUT pin can be left floating. The amplitude of the input signal should be between 500mV and 1.8V and the slew rate should not be less than 0.2V/nS. For 3.3V LVCMOS inputs, the amplitude must be reduced from full swing to at least half the swing in order to prevent signal interference with the power rail and to reduce internal noise. Figure 3A shows an example of the interface diagram for a high speed 3.3V LVCMOS driver. This configuration requires that the sum of the output impedance of the driver (\( R_O \)) and the series resistance (\( R_s \)) equals the transmission line impedance. In addition, matched termination at the crystal input will attenuate the signal in half. This can be done in one of two ways. First, \( R_1 \) and \( R_2 \) in parallel should equal the transmission line impedance. For most 50Ω applications, \( R_1 \) and \( R_2 \) can be 100Ω. This can also be accomplished by removing \( R_1 \) and changing \( R_2 \) to 50Ω. The values of the resistors can be increased to reduce the loading for a slower and weaker LVCMOS driver. Figure 3B shows an example of the interface diagram for an LVPECL driver. This is a standard LVPECL termination with one side of the driver feeding the XTAL_IN input. It is recommended that all components in the schematics be placed in the layout. Though some components might not be used, they can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a quartz crystal as the input.
Schematic Example

Figure 4 (next page) shows an example of an IDT8V41N004I application schematic. The schematic example focuses on functional connections and is intended as an example only. It may not represent the exact user configuration. Refer to the pin description and functional tables in the datasheet to ensure that the logic control inputs are properly set. For example, OE[3:0] and FSEL[1:0] can be configured from an FPGA instead of set with pull up and pull down resistors as shown.

For this device, the crystal load capacitors are required for proper operation. A 12pF parallel resonant 25MHz crystal is used. The load capacitance C1 = C2 = 1pF is recommended for frequency accuracy. Depending on the parasitic of the printed circuit board layout, these values might require a slight adjustment to optimize the frequency accuracy. Crystals with other load capacitance specifications can be used, but this will require adjusting C1 and C2.

The schematic example shows two different HCSL output terminations; the standard termination when the HCSL receiver is on the same PCB as the IDT8V41N004I as well as the termination for a PCIe add-in card.

As with any high speed analog circuitry, the power supply pins are vulnerable to noise. To achieve optimum jitter performance, power supply isolation is required. The IDT8V41N004I provides separate power supply pins to isolate noise from coupling into the internal PLL. In order to achieve the best possible filtering, it is highly recommended that the 0.1uF capacitors at the output of the LC filter be placed on the IDT8V41N004I side of the PCB as close to the corresponding power pin as possible. This is represented by the placement of these capacitors in the schematic.

Do not share ground vias; use at least one ground via per 0.1uF cap or crystal load cap. If space is limited, the ferrite beads, 10uF capacitors and the 0.1uF capacitors connected directly to 3.3V can be placed on the opposite side of the PCB. If space permits, place all filter components on the device side of the board.

Power supply filter recommendations are a general guideline to be used for reducing external noise from coupling into the devices. The filter performance is designed for a wide range of noise frequencies. This low-pass filter starts to attenuate noise at approximately 10kHz. If a specific frequency noise component is known, such as switching power supplies frequencies, it is recommended that component values be adjusted and if required, additional filtering be added. Additionally, good general design practices for power plane voltage stability suggests adding bulk capacitance in the local area of all devices.
Figure 4. IDT8V41N004I Schematic Layout

Note:
PLL_BYPASS, OE_REF, OE[3:0] and FSEL[1:0] are internally pulled down so no external components are required to select the defaults.
If external pull-up/down needed, see "Logic Control Input Examples" shown at left.
PCI Express Application Note

PCI Express jitter analysis methodology models the system response to reference clock jitter. The block diagram below shows the most frequently used Common Clock Architecture in which a copy of the reference clock is provided to both ends of the PCI Express Link.

In the jitter analysis, the transmit (Tx) and receive (Rx) serdes PLLs are modeled as well as the phase interpolator in the receiver. These transfer functions are called H1, H2, and H3 respectively. The overall system transfer function at the receiver is:

$$ H_t(s) = H_3(s) \times [H_1(s) - H_2(s)] $$

The jitter spectrum seen by the receiver is the result of applying this system transfer function to the clock spectrum X(s) and is:

$$ Y(s) = X(s) \times H_3(s) \times [H_1(s) - H_2(s)] $$

In order to generate time domain jitter numbers, an inverse Fourier Transform is performed on X(s)*H3(s) * [H1(s) - H2(s)].

PCI Express Common Clock Architecture

For PCI Express Gen 1, one transfer function is defined and the evaluation is performed over the entire spectrum: DC to Nyquist (e.g. for a 100MHz reference clock: 0Hz – 50MHz) and the jitter result is reported in peak-peak.

PCI Express Gen 1 Magnitude of Transfer Function

For PCI Express Gen 2, two transfer functions are defined with 2 evaluation ranges and the final jitter number is reported in rms. The two evaluation ranges for PCI Express Gen 2 are 10kHz – 1.5MHz (Low Band) and 1.5MHz – Nyquist (High Band). The plots show the individual transfer functions as well as the overall transfer function Ht.

PCI Express Gen 2A Magnitude of Transfer Function

PCI Express Gen 2B Magnitude of Transfer Function

For PCI Express Gen 3, one transfer function is defined and the evaluation is performed over the entire spectrum. The transfer function parameters are different from Gen 1 and the jitter result is reported in RMS.

PCI Express Gen 3 Magnitude of Transfer Function

For a more thorough overview of PCI Express jitter analysis methodology, please refer to IDT Application Note PCI Express Reference Clock Requirements.
VFQFN EPAD Thermal Release Path

In order to maximize both the removal of heat from the package and the electrical performance, a land pattern must be incorporated on the Printed Circuit Board (PCB) within the footprint of the package corresponding to the exposed metal pad or exposed heat slug on the package, as shown in Figure 5. The solderable area on the PCB, as defined by the solder mask, should be at least the same size/shape as the exposed pad/slug area on the package to maximize the thermal/electrical performance. Sufficient clearance should be designed on the PCB between the outer edges of the land pattern and the inner edges of pad pattern for the leads to avoid any shorts.

While the land pattern on the PCB provides a means of heat transfer and electrical grounding from the package to the board through a solder joint, thermal vias are necessary to effectively conduct from the surface of the PCB to the ground plane(s). The land pattern must be connected to ground through these vias. The vias act as “heat pipes”. The number of vias (i.e. “heat pipes”) are application specific and dependent upon the package power dissipation as well as electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. Maximum thermal and electrical performance is achieved when an array of vias is incorporated in the land pattern. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13mils (0.30 to 0.33mm) with 1oz copper via barrel plating. This is desirable to avoid any solder wicking inside the via during the soldering process which may result in voids in solder between the exposed pad/slug and the thermal land. Precautions should be taken to eliminate any solder voids between the exposed heat slug and the land pattern. Note: These recommendations are to be used as a guideline only. For further information, please refer to the Application Note on the Surface Mount Assembly of Amkor’s Thermally/ Electrically Enhance Leadframe Base Package, Amkor Technology.

Figure 5. P.C. Assembly for Exposed Pad Thermal Release Path – Side View (drawing not to scale)
Recommended Termination

*Figure 6A* is the recommended source termination for applications where the driver and receiver will be on separate PCBs. This termination is the standard for PCI Express™ and HCSL output types. All traces should be 50Ω impedance single-ended or 100Ω differential.

![Figure 6A. Recommended Source Termination (where the driver and receiver will be on separate PCBs)](image)

*Figure 6B* is the recommended termination for applications where a point-to-point connection can be used. A point-to-point connection contains both the driver and the receiver on the same PCB. With a matched termination at the receiver, transmission-line reflections will be minimized. In addition, a series resistor (Rs) at the driver offers flexibility and can help dampen unwanted reflections. The optional resistor can range from 0Ω to 33Ω. All traces should be 50Ω impedance single-ended or 100Ω differential.

![Figure 6B. Recommended Termination (where a point-to-point connection can be used)](image)
Power Considerations

This section provides information on power dissipation and junction temperature for the IDT8V41N004I. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the IDT8V41N004I is the sum of the core power plus analog power plus the power dissipation at the outputs. The following is the power dissipation for \( V_{DD} = 3.3V + 5\% = 3.465V \), which gives worst case results.

**NOTE:** Please refer to Section 3 for details on calculating power dissipation at the outputs.

- Power (core)\(_{\text{MAX}}\) = \( V_{DD,\text{MAX}} \times (I_{DD,\text{MAX}} + I_{DDA,\text{MAX}}) = 3.465V \times (121mA + 31mA) = 526.7mW \)
- Power (outputs)\(_{\text{MAX}}\) = \( 44.5mW/\text{Loaded Output pair} \)

If all outputs are loaded, the total power is \( 5 \times 44.5mW = 222.5mW \)

\[ \text{Total Power}_{\text{MAX}} = (3.465V, \text{if all outputs are loaded}) = 526.7mW + 222.5mW = 749.2mW \]

2. Junction Temperature.

Junction temperature, \( T_j \), is the temperature at the junction of the bond wire and bond pad directly affects the reliability of the device. The maximum recommended junction temperature is 125°C. Limiting the internal transistor junction temperature, \( T_j \), to 125°C ensures that the bond wire and bond pad temperature remains below 125°C.

The equation for \( T_j \) is as follows: \( T_j = \theta_{JA} \times P_{d_{\text{total}}} + T_A \)

- \( T_j = \) Junction Temperature
- \( \theta_{JA} = \) Junction-to-Ambient Thermal Resistance
- \( P_{d_{\text{total}}} = \) Total Device Power Dissipation (example calculation is in section 1 above)
- \( T_A = \) Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance \( \theta_{JA} \) must be used. Assuming no air flow and a multi-layer board, the appropriate value is 33.1°C/W per Table 7 below.

Therefore, \( T_j \) for an ambient temperature of 85°C with all outputs switching is:

\[ 85°C + 0.749W \times 33.1°C/W = 109.8°C \]

This calculation is only an example. \( T_j \) will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

3. Calculations and Equations.

The purpose of this section is to calculate power dissipation on the IC per HCSL output pairs.

HCSL output driver circuit and termination are shown in Figure 7.

![Figure 7. HCSL Driver Circuit and Termination](image)

HCSL is a current steering output which sources a maximum of 17mA of current per output. To calculate worst case on-chip power dissipation, use the following equations which assume a 50Ω load to ground.

The highest power dissipation occurs at $V_{DD_{MAX}}$.

\[
\text{Power} = (V_{DD_{MAX}} - V_{OUT}) \times I_{OUT}
\]

since $V_{OUT} = I_{OUT} \times R_L$

\[
\text{Power} = (V_{DD_{MAX}} - I_{OUT} \times R_L) \times I_{OUT}
\]

\[
= (3.465V - 17mA \times 50\Omega) \times 17mA
\]

Total Power Dissipation per output pair = **44.5mW**
