

Description

The 9DBV05x1/9DBV07x1/9DBV09x1 fanout buffers are low-power, high-performance fanout buffers in IDT's Full Featured PCIe family. The buffers have 5, 7 or 9 outputs with each output having an OE# to support the PCIe CLKREQ# function. The devices have 3 selectable SMBus addresses.

PCIe Clocking Architectures

- Common Clocked (CC)
- Independent Reference (IR) with and without spread spectrum (SRIS, SRNS)

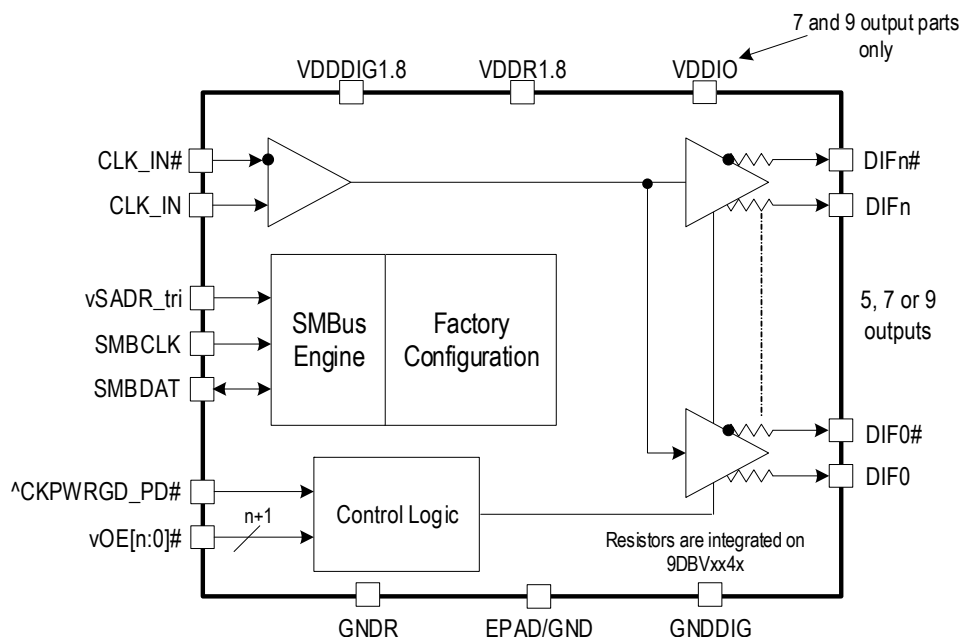

Typical Applications

- Servers/High-performance Computing
- nVME Storage
- Networking
- Accelerators
- Industrial Control

Key Specifications

- PCIe Gen5 CC additive phase jitter < 40fs RMS
- 12kHz-20MHz additive phase jitter = 165fs RMS at 156.25MHz (typical)
- Output-to-output skew < 50ps
- Power consumption as low as 41mW (typical)
- 1MHz to 200MHz operating frequency

Block Diagram

Features

- 5-9 Low-Power HCSSL (LP-HCSSL) outputs
 - 100Ω outputs eliminate 4 resistors per output pair (9DBVxx41)
 - 33Ω outputs eliminate 2 resistors per output pair allowing use in both 85Ω and 100Ω systems (9DBVxx31)
- Easy AC-coupling to other logic families, see application note [AN-891](#)
- Spread spectrum compatible
- OE# pins support PCIe CLKREQ# function
- 3 selectable SMBus addresses
- 3.3V tolerant SMBus interface
- SMBus-selectable features allow optimization to customer requirements:
 - Individual slew rate control for each output
 - Differential output amplitude
 - Device contains default configuration; SMBus interface not required for device operation
- -40°C to +85°C operating temperature range
- Packages: See [Ordering Information](#) for more details

Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the 9DBV05x1/9DBV07x1/9DBV09x1. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

Minimum Voltage	V_{min}		-108	-18		-300		7,8
Crossing Voltage (abs)	V_{cross_abs}	Scope averaging off.	303	405	507	250–550	mV	1,5,7
Crossing Voltage (var)	$\Delta-V_{cross}$	Scope averaging off.		12	50	140	mV	1,6,7

¹ Guaranteed by design and characterization, not 100% tested in production. $C_L = 2pF$ with $R_S = 33\Omega$ for $Z_o = 50\Omega$ (100 Ω differential trace impedance)

² Measured from differential waveform.

³ Slew rate is measured through the V_{swing} voltage range centered around differential 0 V. This results in a $\pm 150mV$ window around differential 0V.

⁴ Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a $\pm 75mV$ window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.

⁵ V_{cross} is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

⁶ The total variation of all V_{cross} measurements in any particular system. Note that this is a subset of $V_{cross_min/max}$ (V_{cross} absolute) allowed. The intent is to limit V_{cross} induced modulation by setting $\Delta-V_{cross}$ to be smaller than V_{cross} absolute.

⁷ At default SMBus settings. 660mV V_{HIGH} is the minimum when V_{DDIO} is $\geq 1.05V \pm 5\%$. If V_{DDIO} is $< 1.05V \pm 5\%$, the minimum V_{HIGH} will be $V_{DDIOmin} - 250mV$. For example, for $V_{DDIO} = 0.9V \pm 5\%$, $V_{HIGHmin}$ will be 860mV - 250mV = 610mV.

⁸ Includes previously separate values of +300mV overshoot and -300mV of undershoot.

¹ The Refclk jitter is measured after applying the filter functions found in PCI Express Base Specification 5.0, Revision 1.0. See the [Test Loads](#) section of the data sheet for the exact measurement setup. The total Ref Clk jitter limits for each data rate are listed for convenience. The worst case results for each data rate are summarized in this table. If oscilloscope data is used, equipment noise is removed from all results.

² Jitter measurements shall be made with a capture of at least 100,000 clock cycles captured by a real-time oscilloscope (RTO) with a sample rate of 20 GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately, jitter measurements may be used with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200MHz (at 300MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5 GT/s data rate, the RMS jitter is converted to peak-to-peak jitter using a multiplication factor of 8.83. In the case where real-time oscilloscope and PNA measurements have both been done and produce different results, the RTO result must be used.

³ SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2 MHz taking care to minimize removal of any non-SSC content.

⁴ Note that 0.7ps RMS is to be used in channel simulations to account for additional noise in a real system.

⁵ Note that 0.25ps RMS is to be used in channel simulations to account for additional noise in a real system.

⁶ The PCI Express Base Specification 5.0, Revision 1.0 provides the filters necessary to calculate SRIS jitter values, however, it does not provide specification limits, hence the n/a in the Limit column. SRIS values are informative only. In general, a clock operating in an SRIS system must be twice as good as a clock operating in a Common Clock system. For RMS values, twice as good is equivalent to dividing the CC value by $\sqrt{2}$. An additional consideration is the value for which to divide by $\sqrt{2}$. The conservative approach is to divide the ref clock jitter limit, and the case can be made for dividing the channel simulation values by $\sqrt{2}$, if the ref clock is close to the Tx clock input. An example for Gen4 is as follows. A "rule-of-thumb" SRIS limit would be either $0.5\text{ps RMS}/\sqrt{2} = 0.35\text{ps RMS}$ if the clock chip is far from the clock input, or $0.7\text{ps RMS}/\sqrt{2} = 0.5\text{ps RMS}$ if the clock chip is near the clock input.

⁷ Additive jitter for RMS values is calculated by solving for "b" where $b = \sqrt{c^2 - a^2}$ and "a" is rms input jitter and "c" is rms output jitter.

Table 12. Phase Jitter Parameters – 12kHz to 20MHz

T_{AMB} = over the specified operating range. Supply voltages per normal operation conditions; see [Test Loads](#) for loading conditions.

Parameter	Symbol	Conditions	Minimum	Typical	Maximum	Specification Limits	Units	Notes
12kHz–20MHz Additive Phase Jitter, Fanout Buffer Mode	t _{jph12k-20MFOB}	Fanout Buffer Mode, SSC OFF, 100MHz		156		N/A	fs (RMS)	1,2,3

¹ Applies to all differential outputs, guaranteed by design and characterization. See [Test Loads](#) for measurement setup details.

² 12kHz to 20MHz brick wall filter.

³ For RMS values, additive jitter is calculated by solving for “b” where $b = \sqrt{c^2 - a^2}$, “a” is rms input jitter and “c” is rms total jitter.
